Marcus's ICP has now stabilized, but he has not totally regained consciousness. He is restless and agitated, and unable to follow directions. His parents stay at his bedside and provide auditory and tactile stimulation, hoping he will eventually respond. He receives physical therapy to prevent contractures and to maintain function. Marcus will need long-term rehabilitation to achieve the best outcome possible after this injury.

What is the role of the nurse in acute care of the child with a severe brain injury? What support does the family need to contribute to the child's care? How would you work with other healthcare providers to coordinate care during the acute care phase? How would you help plan the long-term care for a child such as Marcus?

Children with moderate brain injuries often have long-term problems with attention, problem solving, speed of information processing, and behavior problems (e.g., impulsivity, irritability, apathy, aggression, and social withdrawal). Neuropsychologic testing is needed to identify subtle learning disabilities that are not usually revealed on standardized school achievement tests. Educational accommodations needed are usually different from those made for children with other learning disabilities.

The child or adolescent facing long-term rehabilitation needs support to adjust to the disability and to find the strength to maximize his or her abilities. Identify recreational opportunities for the child with disabilities to promote exercise and self-esteem. The adolescent may need to gain vocational skills and learn to live independently. Refer parents to the Brain Injury Association for further information.

Prevention of brain injury is another important role of the nurse. Encourage parents to obtain protective helmets and require children to use them for bicycling and skateboarding. Parents should be encouraged to wear a helmet themselves as role models. Encourage parents to monitor playgrounds for appropriate use of wood chips or cushioning tiles to reduce the severity of injuries associated with falls.

Evaluation

Examples of expected outcomes of nursing care for the family and child with TBI include the following:

- Cerebral perfusion pressure is maintained at an adequate rate to sustain oxygenation of the brain.
- Muscle function is maintained and physical deformities are prevented with ROM exercises and splinting during the recovery stages of the brain injury.
- Parents are supported through the child's acute recovery phase and learn to provide care the child will need at home.
- The child's school performance is monitored and appropriate educational resources are provided to support the child's learning.

Concussion

A concussion is a mild TBI that usually results from a direct blow to the head, face, neck, or other part of the body. Nearly a half million emergency department visits per year are associated with a concussion in children under age 15 years (Mason, 2013). Organized sports (football, hockey, rugby, soccer, and basketball) and other activities (snow skiing, skateboarding, falls from bicycles, and horseback riding) are associated with concussion.

The blow causes stretching and bruising of brain tissue that disrupts nerve transmission and metabolic function, but no structural abnormality is seen with radiographic imaging. Most children have concussion symptoms for up to 7 to 10 days, but their cognitive recovery often takes longer.

The child with a concussion has a rapid onset of short-term functional impairment that may or may not involve loss of consciousness and cognitive, physical, emotional, and sleep symptoms that may persist for minutes to months (Meckler, 2014). Signs and symptoms may include the following:

- *Physical*—headache, sensitivity to light or noise, dazed, visual problems, balance problems, fatigue, and nausea and vomiting
- *Cognitive*—feeling foggy or sluggish, difficulty concentrating and remembering, confused about recent events, answers slowly
- *Emotional*—irritable, sad, nervous, more emotional than usual
- *Sleep*—drowsy, sleeps more or less than normal, difficulty falling asleep

Pediatric concussive syndrome is thought to be caused by an injury to the brainstem and occurs in children younger than age 3 years. Toddlers seem stunned at the time of injury, but have no loss of consciousness. Later, these children become pale, clammy, and lethargic, and they may vomit.

Initial sideline evaluation of the child injured in an organized sport involves removing the child from play, and using a checklist to assess orientation, recent and remote memory, new learning, concentration, and balance (Harmon et al., 2013). Questions are asked about events before and after the injury to help identify amnesia, an important sign of a more serious injury. A history is taken and physical examination performed in the health center or emergency department. Because no findings are typically found on CT and MRI, radiologic imaging is not performed unless an intracranial structural injury is suspected. Computerized neuropsychologic tests are available to test a high school athlete's baseline performance for comparison after concussion to monitor recovery.

Treatment is supportive. Children are observed in the emergency department for several hours before being sent home with instructions to the parents to watch them closely for decreased responsiveness. The child who is unconscious for more than 5 minutes or has amnesia of the event may be admitted to the hospital or be observed in a short-stay unit to rule out other injury. All cognitive activities are limited in the first few days after injury, including time out of school, video games, watching television, and using a computer (Meckler, 2014). Before returning to organized sports, the child should be symptom-free and using no analgesia for headache. Symptoms usually disappear within several weeks but may last up to 6 months. Physical activities are gradually increased, and if symptoms recur, return to play is further delayed.

Even though the child looks normal following a brain injury, ensure that parents and teachers know that brain healing takes up to 6 weeks. Typical behaviors during this healing period may include tiring easily, memory loss or forgetfulness, easy distractibility, difficulty concentrating, difficulty following directions, irritability or short temper, and needing help starting and finishing tasks. Return the child to a full school schedule gradually to prevent fatigue and frustration. Educational assessment should be initiated if recovery takes longer than 6 weeks.

Young athletes who return to play too soon may have a delayed reaction time and be at greater risk for a second concussion. Long-term neurologic problems may result from recurrent concussions.

Professionalism in Practice Concussion Management in the School Setting

The American Academy of Neurology recently updated guidelines for evaluation and management of concussions (Giza et al., 2013). Many activities in the school setting (e.g., sports, physical education, and playtime) can place the child at risk for a concussion. School nurses collaborate with school staff members, athletic trainers, and parents to prevent concussions and to assess the child with a potential concussion. Nurses may also coordinate the development of an individualized health plan to accommodate the child's graduated return to school and sports. They also help the teachers understand the emotional and behavioral responses of the child returning to the classroom (National Association of School Nurses [NASN], 2012).

Scalp Injuries

Injuries to the scalp, which can be caused by falls, blunt trauma, or penetration of a foreign body, are usually benign. Bleeding may be extensive, but hypovolemia or shock is uncommon unless the patient is an infant.

Lacerations should be irrigated with copious amounts of sterile normal saline solution and inspected for bony fragments or depressions, CSF leakage with a dural tear, or debris. If the injury is simple, the laceration can be sutured and the child discharged from the emergency department. If more severe, a neurosurgeon should be consulted.

Skull Fractures

A fracture to any of the eight cranial bones requires considerable force:

- *Linear fracture*—most common type of fracture, can potentially be caused by child abuse. May have overlying hematoma or soft tissue swelling; usually no symptoms.
- *Depressed skull fracture*—break in skull itself or an area shattered into many fragments. Pieces of bone may be depressed into brain tissue with hematoma forming on top.
- *Basilar fracture*—fracture at the base of the skull; may involve the frontal, ethmoid, sphenoid, temporal, or occipital bones; a dural tear may be present; increases risk for meningitis. The child may have blood behind the tympanic membranes, CSF leakage (yellow to amber fluid) from the nose or ears, periorbital ecchymosis (raccoon eyes), or bruising of the mastoid (Battle sign).

Any area of the skull with swelling or a hematoma should be evaluated for possible fracture. Diagnosis is made by visual inspection, palpation, skull radiograph, or CT scan.

Treatment includes neurosurgical consultation. Surgery may be required for debridement or to elevate bone fragments of a

depressed skull fracture. Tetanus prophylaxis and antibiotic therapy may be prescribed in some cases. Some skull fractures may be associated with intracranial bleeding, cranial nerve injuries, and posttraumatic epilepsy.

Penetrating Injuries

Gunshot wounds to the head can damage brain tissue, bone, and blood vessels. The child's level of consciousness quickly deteriorates because of the edema surrounding the penetration tract.

CT scans evaluate gunshot trauma and pinpoint the location of bullet and bone fragments as well as damaged brain tissue. Surgery is performed to debride the tract, evacuate any hematomas, and remove accessible bone or bullet particles. A high percentage of these children die. Those who survive may suffer multiple focal deficits and seizures.

Impalement injuries may occur in children in association with projectiles, dog bites, or other sharp objects. All objects must be left in place and removed in the operating room by a neurosurgeon. The child is at high risk for focal injury and infection. After surgery, children are managed in the same manner as other postoperative brain injuries, with attention focused on level of consciousness, management of increased ICP, and infection control.

Spinal Cord Injury

Injury to the spinal cord is a rare condition that causes major lifelong disabilities and a shortened life. Only 2% to 5% of spinal cord injuries occur in the pediatric population, and more commonly involve cervical spine injury (Pettiford et al., 2012). Mechanisms of injury in children and adolescents include motor vehicle crashes (passenger and pedestrian), recreational activities, and violence (child abuse, stabbing, and gunshot wounds).

The mechanism of injury and direction of forces determine the type of lesion that occurs (Figure 27–15). Hyperflexion

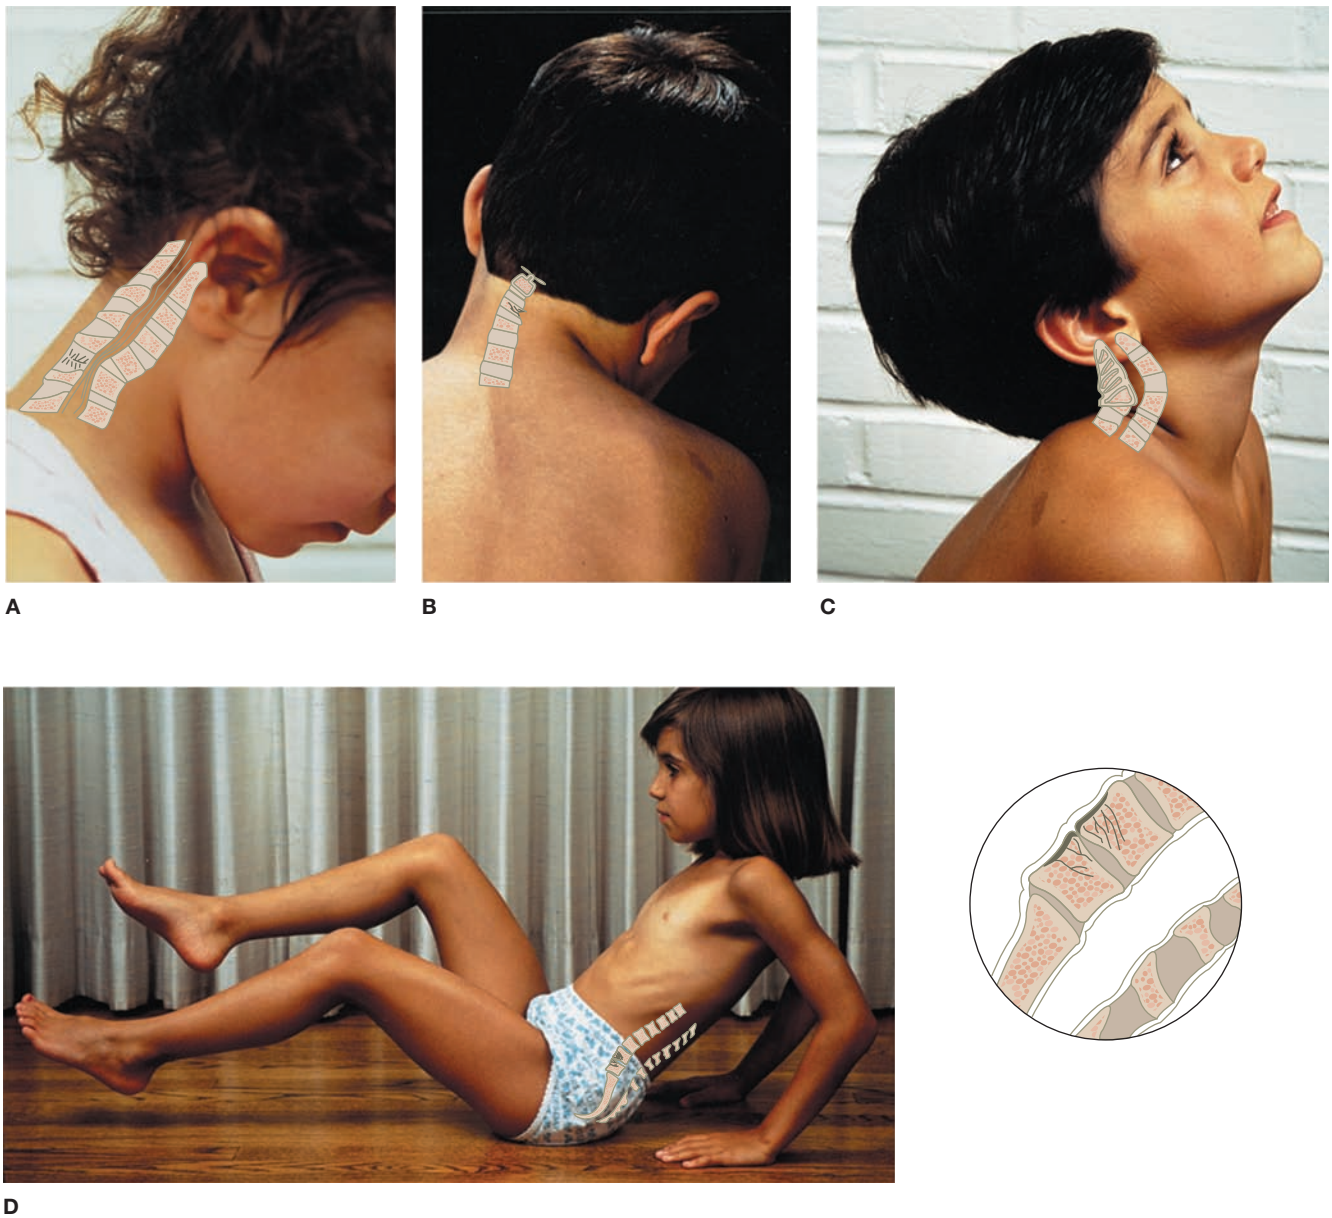

Figure 27–15 **Mechanics of injury to the spinal cord. *A*, Hyperflexion. *B*, Lateral flexion. *C*, Hyperextension. *D*, Compression.**

injuries (e.g., bending around a car safety seat belt) produce tears or avulsions and fractures of vertebral bodies, as well as subluxation and dislocation. Rotation may cause joint dislocations or unstable spinal fractures. Hyperextension may result in the so-called hangman's fracture, ligament tears, avulsion fractures of vertebral bodies, and central or posterior spinal cord syndrome. Compression injuries may occur when a child falls from a height. Young children are prone to specific kinds of spinal cord injuries because of the mobility and flexibility of their spinal column.

Spinal cord injuries are classified as complete or incomplete. Complete lesions are irreversible and involve a loss of sensory, motor, and autonomic function below the level of the injury. Incomplete lesions involve varying degrees of sensory, motor, and autonomic function below the level of injury. Autonomic dysfunction is associated with hypotension, loss of bladder and bowel control, and loss of environmental thermoregulatory function. The higher the level of spinal cord injury, the more severe the neurologic damage. Table 27–17 describes the spinal cord injuries that occur in children.

At the time of injury due to compression, shear injuries, or other injury, the child is flaccid and loses reflexes below the level of the lesion. Inflammation causes a secondary injury, resulting in ischemia and necrosis. **Spinal shock**, spinal cord concussion resulting in a transient suppression of nerve function below the level of the acute injury, occurs. Some return of function may occur within the first 72 hours of injury in an incomplete lesion. As neurologic recovery begins, spinal reflex activity returns and increasing spasticity is seen below the level of the injury.

The child can experience neurogenic shock in which there is loss of vasomotor tone and sympathetic innervations of the heart, resulting in hypotension, bradycardia, and peripheral vasodilation (a form of distributive shock). See Chapter 21. Priapism may be seen. Respiratory compromise may be present because of paralysis of the diaphragm.

Diagnosis is made by observation, neurologic examination, and radiologic studies of the cervical, thoracic, and lumbosacral spine to determine if a vertebral fracture or compression on the spinal cord is present. When a child with a suspected spinal cord injury was immobilized by prehospital providers, cautious physical and radiologic evaluations are needed before the child is unrestrained. In addition, CT scanning, MRI, fluoroscopy, or myelography may be performed. Some young children have spinal cord injury without radiographic abnormality (SCIWORA) on a plain radiograph, but an MRI can detect the injury to ligaments and soft tissues.

Growth and Development

The vertebrae are not fully ossified in children younger than 9 years. The facet joints are more shallow and horizontal, allowing them to slide over each other more easily as the ligaments stretch. The young child's head is relatively large compared to the strength of the neck muscles. When the neck muscle strength is exceeded, the ligaments supporting the vertebrae can stretch much more than the spinal cord, leading to spinal cord tearing. Injuries to children under age 9 are more likely to occur at the C1 to C3 level, and at the C4 to C6 level in children ages 9 to 15.

Spinal injuries are managed aggressively. The child with a confirmed spinal cord injury may be placed in external immobilization with a halo device. Surgery to reduce and internally fixate the fracture is performed for unstable fractures, dislocations, and progressive deformity. Decompression of the spinal cord and nerve roots may be performed if transection is not complete or if compression by a clot, herniated disk, or other lesion is present and can be relieved.

To decrease neurologic sequelae in children with motor deficits, a high-dose methylprednisolone is often administered intravenously if started within 8 hours of injury. Evidence does not clearly indicate a benefit to this treatment, and adverse effects include increased risk of infection, hyperglycemia, and gastrointestinal bleeding (Pettiford et al., 2012). Gastrointestinal prophylaxis is started to reduce the risk for an ulcer. Atropine and norepinephrine may be given to manage spinal shock. IV fluid resuscitation is also performed if the child could have

TABLE 27–17 Spinal Cord Injuries in Children

SPINE REGION	INJURY CHARACTERISTICS
Cervical	• Site of the majority of spinal injuries in children under 10 years • Injury above C3 segment causes respiratory arrest and death without ventilatory support; many of these injuries are fatal • Diaphragm function is present when injury is at C5 level • **Tetraplegia**, can have loss of sensation and function of the head and neck and upper and lower extremities • Loss of sphincter function • Sensory level lost below the sternum
Thoracic	• More commonly, the site of spinal injuries in children between 8 and 14 years • Full control of upper extremities including hands • Poor trunk balance
Thoracolumbar	• Full control of muscles in abdomen and upper back • Good trunk balance
Lumbar	• Injuries at the L1–L3 level may occur in children 4–8 years using a car lap belt rather than a car safety seat • Below L3 may have functioning of muscles in upper leg • Loss of ankle and foot control

hypovolemic shock from other injuries. Complications of spinal cord injury include:

- Impaired respiratory function due to a paralyzed diaphragm or diminished vital capacity
- Scoliosis if injury occurs before the skeleton is mature
- Hip instability due to poor acetabular development
- Pathologic fractures of the long bones due to immobilization hypercalcemia
- Pressure sores
- Deep vein thrombosis
- Autonomic dysreflexia

Spasticity, muscle atrophy, increased risk of respiratory problems, weight gain, osteoporosis, and other skeletal problems are long-term issues for many children. The goal of rehabilitation is to promote independence in daily activities, as well as mobility, strength, power, and endurance.

SAFETY ALERT!

Autonomic dysreflexia is a condition associated with injuries above the T6 level. It becomes a medical emergency when overactivity of the autonomic nervous system causes an abrupt onset of hypertension, cardiac arrhythmia, pupillary constriction, severe headaches, flushing above the level of the spinal cord lesion, and sweating. Below the level of the lesion, the skin is pale and cool with piloerection. Common triggers are constipation, a full bladder, or a pressure ulcer. Treatment involves positioning the patient upright, loosening tight clothing, emptying the bladder, eliminating any precipitating stimulus, and administering antihypertensive medication. Prevention of autonomic dysreflexia involves an effective bowel and bladder program and prevention of pressure ulcers (Stephenson & Berliner, 2014).

Nursing Management

For the Child With Spinal Cord Injury

HOSPITAL-BASED NURSING CARE

Nursing care focuses on monitoring vital signs, meeting nutritional needs, maintaining skin integrity, promoting independent functioning, providing emotional support, and promoting rehabilitation.

Be alert for any changes in vital signs, especially those that may signify increased respiratory difficulty, neurogenic shock (hypotension, bradycardia, and peripheral vasodilation), increased ICP (see Table 27–4), or autonomic dysreflexia. Monitor intake and output. Monitor bladder and bowel function. Assess the skin for integrity.

With higher cervical injuries, assess the cranial nerves as they may be affected by swelling around the spinal cord. Note the return of reflexes and change from flaccid tone to spasticity. Identify any changes in level of sensation or motor function. Carefully check the immobilizing device to ensure that the spine stays stable.

Some children with cervical lesions have tracheostomies performed to help maintain airway patency; others with high cervical lesions are dependent on ventilators. Keep suctioning equipment and other emergency equipment at the bedside at all times.

Ensure adequate nutrition. A child with complete paralysis may require a gastrostomy tube. When the child begins to eat, feed soft foods slowly as the child may have some swallowing difficulties.

Prevent skin breakdown (see Chapter 31). Observe surgical sites for signs of infection or inflammation. Provide regular traction pin site care according to hospital guidelines. Establish a schedule for patient repositioning.

Promote independent functioning by reinforcing the exercises and skills learned in physical and occupational therapy. Use supports, boots, footboards, splints, and braces as recommended by the therapists to prevent contractures. If hand mobility is limited, explore options for independence. Encourage the child to be as independent as possible in a wheelchair. An important mobility goal is to achieve wheelchair transfer and to perform self-care. Identify adaptive equipment that makes these goals possible.

Achieving bowel and bladder control may be difficult. Regular intermittent catheterizations may be necessary if urinary retention occurs (see the *Clinical Skills Manual* SKILLS). Anticipate that constipation will occur and initiate bowel training with a diet high in fiber and the use of stool softeners.

Therapeutic play appropriate for the child's developmental level is an important part of the healing process. Provide as many normal activities for the child as possible, but do not give the child tasks that will be difficult to complete. Child-life teachers or tutors can help the child keep up with schoolwork.

Television, DVDs, computer games, Internet connections, and music can offer diversion for prolonged hospitalization. Children with paraplegia can learn to use their arms and hands to play interactive games. Devices can also be adapted so that the child can play computer games or manipulate the television or radio. Identify assistive technology that may help the child with tetraplegia gain some level of independence.

Support the child emotionally. Encourage the child to meet small, short-term goals, including those that involve self-care. Encourage the child to express fears and frustrations.

Be compassionate and understanding. Encourage siblings to visit, answer their questions honestly, and help them to discuss their feelings. Involve the parents and siblings in the child's care as much as possible. When appropriate, encourage them to help with activities of daily living.

DISCHARGE PLANNING AND HOME CARE TEACHING

Many children are discharged to inpatient rehabilitation facilities. Assist with arrangements for the transfer. Work closely with the child, parents, and other members of the healthcare team concerning placement. Home care needs, reintegration into educational programs, and safety issues should be identified and addressed well in advance of discharge from the rehabilitation facility. Refer families to social services, family counseling, and support groups if indicated.

Hypoxic-Ischemic Brain Injury (Drowning)

Drowning is defined as the process resulting in primary respiratory impairment from submersion/immersion in a liquid medium. *Submersion injury* is the term used when the child survives. Drowning, a leading cause of unintentional injury death for children of all ages between birth and 19 years, caused 866 deaths in the United States in 2013. Children 1 to 4 years and 15 to 19 years old had the highest rate of drowning deaths in 2013 (National Center for Injury Prevention and Control, 2015). Boys are affected more frequently than girls. For every death, an additional two children are hospitalized for nonfatal drowning events (Bowman, Aiken, Robbins, et al., 2012).

In young children, drowning is associated with bathing and falling in water (e.g., pools or large buckets). Older children are more likely to drown in open water, potentially associated with risk-taking behaviors, seizures, or alcohol use (Bowman et al., 2012).

It takes only enough water to cover the nose and mouth for a child to drown. The child trapped in water panics, struggles, tries to move using swimming motions, and holds the breath. The child aspirates a small amount of water from the oropharynx, causing a laryngospasm that lasts no more than 2 minutes and hypoxia. Because of increasing panic and hypoxia, the child swallows more liquid. As the laryngospasm passes, the child breathes water into the lungs. The child may also vomit and aspirate stomach contents. Aspirated water damages the lung surfactant and impairs alveolar gas exchange. Hypothermia may result because the child's body cools faster in water than in air, and systemic perfusion decreases as a result (see Chapter 31). With increasing hypoxia, the cardiac muscle becomes impaired and ultimately the heart stops.

Anoxia associated with drowning leads to cerebral edema and increased ICP and secondary cerebral injuries. With aggressive cardiopulmonary resuscitation the child may survive, but usually with neurologic impairment.

The signs and symptoms of submersion vary by the length of time underwater, temperature of the water, response to the episode, and the initial scene treatment. The child who has been submerged may be apneic and pulseless. When submerged for short periods (less than 5 to 10 minutes and resuscitated at the scene), children may have few symptoms and fully recover without neurologic impairment. Signs and symptoms in the rescued child may be decreased level of consciousness ranging from stupor to total unresponsiveness, apnea or irregular respirations, gastric distention, and seizures. The child submerged for longer than 10 minutes or who has delayed cardiopulmonary resuscitation is more likely to have neurologic impairment or to die.

Immediate cardiopulmonary resuscitation (CPR) performed at the scene is associated with the best outcomes. Emergency personnel with a defibrillator should assess the heart rhythm and defibrillate if ventricular fibrillation is present. The child should be transported to the hospital even if the child begins breathing spontaneously. Initial emergency treatment is 100% oxygen and rewarming. The airway may be secured with an endotracheal tube.

SAFETY ALERT!

All submersion victims should be observed in the hospital for 6 to 8 hours, even when initially asymptomatic. Signs of respiratory distress and cerebral edema develop within this timeline, and immediate care can be provided as needed.

The child who has a serious anoxic injury is cared for in the ICU. Mechanical ventilation may be used to keep the alveoli open, to promote adequate oxygenation, and to prevent respiratory acidosis. Treatment for cerebral edema is initiated (see the earlier section on care of the child with a traumatic brain injury).

Nursing Management

Nursing care of the child who survives a submersion incident focuses on monitoring the child's neurologic and cardiopulmonary status and providing emotional support to the family.

Assess the child's responsiveness, spontaneous respiratory efforts, oxygenation, and vital signs. Perform frequent neurologic status assessments. Attach a cardiorespiratory monitor and pulse oximeter for continuous patient assessment information.

Implement the nursing interventions for a child with altered states of consciousness as described earlier in this chapter. If cerebral edema develops, implement nursing interventions as described in the earlier section on care of the child with a traumatic brain injury.

Provide emotional support to the family. Be nonjudgmental and provide a forum for parents to express their feelings. Reassure parents who exhibit guilt reactions that their child is receiving all possible medical treatment. Parents may be faced with an unknown prognosis. Encourage them to seek assistance from social workers, members of the clergy, close friends, and relatives. Arrange for appropriate referrals. If the child's prognosis is poor, an ethics consultation may be offered to educate the family about options for decision making regarding sustaining or terminating life support (see Chapter 13).

Identify and address rehabilitation or home care needs well in advance of discharge. Assist with arrangements for the child with minor deficits. Assign a case manager to the child with significant neurologic impairments so that long-term care options can be explored. Inpatient or outpatient rehabilitation options should be matched to the child's needs and family resources.

Drowning can be prevented by education, legislation, and changes in the environment. Pool owners should erect climb-proof 5-foot fences around all four sides of the pool. If fencing is on three sides, with the house serving as the fourth side, the house door to the pool area should be kept locked and have an alarm. Local ordinances may require such fences. Ensure that hot tubs and pools have drain covers or other safety devices that prevent a child from getting a limb or hair entrapped in a drain. Adolescents should learn the dangers of mixing alcohol or drugs and swimming. Keep 5- and 10-gallon buckets empty when not in use. Emphasize the importance of closely supervising children when near or in the water, whether at pools, at the beach, or in the bathtub. Children with seizure disorders should always have a buddy when swimming.

Chapter Highlights

- The nervous system is complete with all nerve cells at birth. Myelination continues throughout childhood.
- Altered level of consciousness is caused by infection, trauma, hypoxia, poisoning, seizures, alcohol or substance abuse, endocrine or metabolic disturbances (e.g. diabetic ketoacidosis), electrolyte or acid–base imbalance, intracranial space-occupying lesion, stroke, and a congenital structural defect.
- Emergency care for the child or adolescent with a prolonged generalized seizure includes airway management, supplemental oxygen, intravenous benzodiazepines, and careful monitoring of vital signs and motor activity. Carefully document the duration of the seizure or series of seizures to detect status epilepticus.
- Neurologic damage from bacterial meningitis often occurs in infants and young children despite early, aggressive management. Complications may include hearing impairment, gross neurologic deficits, and behavioral and intellectual disorders.
- Encephalitis is an acute inflammation of the brain often caused by a virus that is transmitted by a mosquito, such as West Nile virus and Western Equine virus. Presenting signs include a severe headache, fever, irritability, and altered mental status.
- Reye syndrome is an encephalopathy with a high mortality rate that is associated with aspirin use for a mild viral illness. Because most parents give children acetaminophen or ibuprofen rather than aspirin for flulike symptoms and varicella, Reye syndrome has become rare.
- Guillain-Barré syndrome is a disorder of deteriorating motor function and paralysis that progress in an ascending pattern, paresthesia, and areflexia. It may be caused by an autoimmune response to an infectious organism, usually within 1 to 3 weeks of a gastrointestinal or respiratory illness.
- More than 75% of children experience a headache by age 15 years. Types of benign headaches include migraines, inflammatory (sinusitis), and tension.
- Microcephaly is a small brain that may be caused by genetic transmission, fetal or postnatal insult, or intrauterine infection.
- Hydrocephalus is caused by the blockage of cerebrospinal fluid flow through normal channels and pathways or the impaired absorption of cerebrospinal fluid in the subarachnoid space and the arachnoid villi. It can be associated with a congenital condition or acquired from meningitis or intraventricular hemorrhage, tumor, or structural deformity.
- The more common types of neural tube defects include anencephaly (no development of the brain above the brainstem), encephalocele (protrusion of meningeal or skin-covered brain through the skull), and myelomeningocele or spina bifida.
- Myelomeningocele or spina bifida is a malformation of the vertebrae and spinal canal with a protrusion of a meningeal sac filled with a portion of the spinal cord. It is the most common developmental disorder of the CNS.
- Positional plagiocephaly, an asymmetric flattening of the occiput, is associated with sleep position to prevent sudden infant death syndrome or with neck problems such as congenital torticollis. The weight of the infant head sometimes flattens the skull. Strategies to encourage the child to change the position of the head may help reduce its occurrence.
- Neurofibromatosis 1 is characterized by multiple café au lait spots, darker than the surrounding skin, that are 5 mm (0.2 in.) or larger in infants but grow to 15 mm (0.6 in.) in diameter during adolescence. Multiple benign tumors grow on or under the skin beginning during puberty.
- Most cases of cerebral palsy are characterized by spasticity and a lack of coordination. The risk for cerebral palsy is increased with prematurity, intraventricular hemorrhage, intrauterine infection, neonatal sepsis, and hyperbilirubinemia.
- Traumatic brain injury is a leading cause of death and disability during childhood. It results from falls, motor vehicle crashes, sports injuries, and child abuse.
- Concussions result from the stretching, compression, and shearing of nerve fibers after an impact injury to the head that causes signs such as transient altered mental status, amnesia, dizziness, and impairment of memory, orientation, and balance.
- Spinal cord injuries, although relatively rare in children, often result from significant forces such as from motor vehicle crashes. Because of the child's larger and heavier head and weaker neck muscles, cervical spine injuries are more common.
- Children who have the best outcomes following drowning include those submerged less than 5 minutes who receive immediate cardiopulmonary resuscitation.

Clinical Reasoning in Action

Abigail, a 3-year-old with myelodysplasia, is seen every few months with her parents in the multidisciplinary spina bifida clinic where you work. Her lesion is at the L3 level, so she can flex her hips and extend her knees, but her ankles and toes are paralyzed. She also has a ventriculoperitoneal shunt for hydrocephalus. She uses lower leg braces and a walker to mobilize and has minimal sensation in her lower legs and feet. Her bladder and bowel sphincters are also affected, so Abigail and her parents have worked hard to establish bowel control with a high-fiber diet and by establishing specific times for bowel evacuation. Abigail's parents learned to perform intermittent catheterization for bladder control to reduce the risk for kidney damage.

Her health history reveals she has experienced a case of otitis media since her last visit and responded well to antibiotics. Her legs are well protected by stockings to reduce rubbing by her braces. Her gait is becoming steadier with the walker, and her parents are encouraging exercise of her arms and upper trunk with swimming. You encourage Abigail's parents to promote her cognitive development with age-appropriate games and interaction with siblings. Her parents plan to enroll her in preschool in the fall.

1. What are the safety issues to discuss with Abigail's parents about spina bifida?
2. Describe spina bifida and its relationship with hydrocephalus.
3. Identify important health promotion issues to discuss with Abigail's parents.
4. Describe the issues that need to be addressed in planning for an IEP and individual health plan when Abigail enters preschool.

Chapter 28
Alterations in Mental Health and Cognitive Function

Oleg Golovnev/Shutterstock

We've been so worried about Cassandra. After being in the car crash, she has become so frightened of everything. She wakes up at night screaming and has lost interest in school and friends. We hope that her work with the therapist will help decrease her fears and get her involved in all of her activities again.

—Mother of Cassandra, 9 years old

Learning Outcomes

28.1 Define mental health and describe major mental health alterations in childhood.

28.2 Discuss the clinical manifestations of the major mental health alterations of childhood and adolescence.

28.3 Plan for the nursing management of children and adolescents with mental health alterations in the hospital and community settings.

28.4 Describe characteristics of common cognitive alterations of childhood.

28.5 Use evidence-based practice to plan nursing management for children with cognitive alterations.

28.6 Establish and evaluate expected outcomes of care for the child with a cognitive alteration.

This chapter will provide the knowledge and tools needed to provide appropriate care for children with alterations in mental health and cognition. Mental health care is provided by psychiatric–mental health specialists, so the nurse's role often centers on identification, support of the therapy, teaching, and referral. Cognitive conditions are commonly managed by the family and the school personnel. The nurse also forms partnerships with families and school personnel to plan and evaluate care for the child with cognitive conditions such as intellectual disability (formerly called *mental retardation*). A thorough knowledge of development is a prerequisite to understanding both mental health alterations and cognitive conditions since developmental status is often altered in both mental health and cognitive conditions. Review Chapter 4 as needed to understand the relationships of development to the conditions described in this chapter.

Mental Health Alterations of Children and Adolescents

Mental health is foundational to a sense of personal well-being, physical health, and psychologic stability. It involves successful engagement in activities and relationships and the ability to

Text continues on page 792

FOCUS ON:
Mental Health and Cognition

Pediatric Differences

Some mental health and cognitive conditions in children originate from a genetic or physiologic cause—for example, intellectual disability (previously called *mental retardation*) and childhood schizophrenia. Often the family and surrounding environments in which children live influence their characteristics and contribute to dysfunctions such as anxiety, depression, and posttraumatic stress disorder. A unique and challenging interplay of genetics and environment influence mental health and cognitive conditions, thus making diagnosis and treatment challenging.

Children differ from adults both in mental health care needs and in the types and progression of mental health disruptions. During childhood, the necessity for bonding and attachment to significant adults forms the foundation of the child's healthy mental development. Therefore, young children rely on adults for establishment of mental health. The child's unique genetic makeup couples with these environmental factors, thereby contributing to a state of mental health. Cognitive disorders are also a result of a unique interplay of genetic and environmental causes. The brain develops from the fetal neural tube early in development, with much critical embryology occurring in the fourth to sixth week of gestation, at which point many women are unaware that they are pregnant. During this time, the brain is not protected by the blood–brain barrier and is at risk for injury from the fetal environment. Environmental conditions such as maternal alcohol ingestion or intake of certain medications can influence the developing fetus's brain.

In addition, children with mental health alterations sometimes display different clinical manifestations for mental illness than adults; therefore, diagnosis is difficult and challenging. For example, a child with a tic syndrome may be mistakenly diagnosed as hyperactive, and the treatment therefore would not be appropriate to the underlying condition.

At birth the brain makes up about 25% of body weight; this percentage decreases to about 2% of weight by adulthood. Most of the brain structure is present at birth, but during the first 5 years of life the brain continues to develop and mature as the young child gains fine and gross motor, social, and language skills. Development and differentiation occur during childhood spurts with fine motor skills improvement and during adolescent years when perception, motor function, and advanced thinking processes further develop. The child remains vulnerable to external forces during periods of brain growth and development. The influence of drugs, poor nutrition, traumatic brain injury, and absence of emotional nurturance are all examples of factors that can interfere with healthy brain and cognitive development.

Examples of diagnostic and laboratory tests used for mental health and cognition include magnetic resonance imaging (MRI), radiograph (x-ray), electroencephalogram, positron emission tomography (PET) scan, neuropsychologic testing, and toxicology screening (see Appendix E). Use *Assessment Guide: The Child With an Alteration in Mental Health or Cognition* to perform a nursing assessment.

The purpose of this chapter is to provide the knowledge and tools that can help you provide appropriate care for children with alterations in mental health or cognition. Much of the care for mental health alterations is provided by psychiatric–mental health specialists, so the nurse collaborates with these specialists to identify problems, support and carry out therapy, provide education for the family, and refer the family to appropriate resources. Children with mental health or cognitive disorders are sometimes hospitalized, visit well-child clinics, and attend schools. Nurses in all settings must gain the skills to provide care for these children. See Chapter 14 for a description of eating disorders.

The nurse collaborates with families and school personnel to plan and evaluate care for the child with cognitive conditions such as intellectual disability. A thorough knowledge of development is a prerequisite to understanding both mental health disruptions and cognitive conditions, because developmental status is often altered in both mental health and cognitive conditions.

Most mental health conditions are treated in community settings, and nurses in these settings play an active role in the treatment and support of the child and family. Nurses may function as case managers, assisting a family to deal with all areas of the child's care. Occasionally a child is hospitalized for treatment of a significant mental health disruption or is hospitalized for treatment of another health problem and requires continued mental health services.

ASSESSMENT GUIDE | The Child With an Alteration in Mental Health or Cognition

Assessment Focus	Assessment Guidelines
History	• Describe prenatal care and problems. Was there any trauma at birth? • Is there a diagnosed mental health disorder in the child or other family members? • Is there a history of any neurologic injuries or diseases such as cancer? • What medications is the child taking? What medications have been taken in the past? • Has there been exposure to environmental pesticides or other chemicals?
Growth	• Is growth progressing at a uniform rate so that the child maintains a similar growth percentile? • Is head circumference within normal limits?

(*continued*)

Assessment Focus	Assessment Guidelines
Development	• Perform regular developmental screening to identify any variations from expected developmental milestones. Further testing is required if screening suggests any abnormalities. • What is the progression of skills reported by the family? • Are there any unusual capabilities or deficits? • Inquire about progression in school and extracurricular activities.
Social skills	• Describe the relationship between the child and significant adults. Is close attachment evident? Are there signs of attachment disorders such as lack of eye contact, smiles, or response to others in the environment? • Describe the school-age child's daily schedule, including family and peer activities. Does the child have friends and engage in several activities with them on a regular basis? Does the child generally interact well with others? Has the child recently had a change in school performance? • Ask the teen to describe daily activities and friends. Is there a combination of peer and family influence on personal decision making?
Affect	• Describe facial expression and response to nurse. • Observe body size, position, and posture. • Are interaction behaviors typical for the setting and age of the child? • Does the child display interest in surroundings? • Is the child dressed in an appropriate manner? Does the child establish eye contact?
Appearance	• Is the child's clothing appropriate for age, setting, and developmental level?
Behaviors	• Describe level of consciousness and interaction with surroundings. • Inquire about recent reported changes in behavior (e.g., sleep, eating patterns, communication with others, school performance, friendships, risky activities). • Has the child or parent identified any problem behaviors? • Are any particular events associated with the problem behaviors?
Life events	• Has the child or family experienced recent stress or trauma? • Have there been any changes in family structure? • Evaluate chronic health conditions in family members.

adapt and cope with change. **Cognition** refers to the change in thought, intelligence, and language that occurs over time as brain maturation and life experiences interact to mutually influence child performance (Santrock, 2011).

Approximately 15 million children in the United States suffer from mental illness that is severe enough to impair functioning at home or school. Overall, about 1 in 5 children and adolescents has a mental health disorder, and 1 in 10 has a disorder that profoundly interferes with daily functioning. Up to 75% to 80% of children with mental health disorders do not receive adequate comprehensive or multidisciplinary treatment, leading to unmet mental health needs. (National Center for Children in Poverty, 2014).

Etiology and Pathophysiology

From the ages of 10 to 21 years, mental health issues are among the top two leading causes of hospitalization (see Chapter 1). This high rate of hospitalization suggests that children are not receiving clinical therapy early, when outpatient care is appropriate and prognosis is best.

Certain population groups are at increased risk for mental disorders. Children from homes with low income are twice as likely to have mental health disruptions. Approximately 50% of children in the child welfare system and 70% of youth in the juvenile justice system have mental disorders (National Center for Children in Poverty, 2014). Children with special healthcare needs and those living in military families have particular barriers to accessing mental health services. More information about military family stress is found in Chapter 17.

There is a wide array of cognitive challenges for children, from conditions that have a genetic basis to those that are caused by prenatal or postnatal trauma or infections. Developmental surveillance often reveals cognitive disorders so that early intervention can be planned in order to maximize potential.

During all healthcare visits, mental health screening should be integrated into care so that alterations can be identified. See Chapters 7, 8, and 9 for specific questions to ask during health promotion and health maintenance visits.

Clinical Manifestations

The manifestations of mental health alterations in children are varied, but most can be identified through careful developmental and behavioral screening. Children with mental health conditions often do not display the usual developmental milestones at the times predicted. They may have social interaction problems with family members or other people, or they may have demonstrated a change in performance from former developmental achievement. Functional patterns of living such as the ability to

feed and care for self, regulation of sleep and nutritional intake, and the ability to self-regulate during activities may be lacking. Repetitive actions, behavioral instability and outbursts, and withdrawal are other important signs of mental health disruption.

Clinical Therapy

Diagnosis of mental health conditions involves careful physical and psychologic assessment. Studies such as magnetic resonance imaging (MRI), radiographs, electroencephalograms, and toxicology screening may be useful. Mental health is linked to development so developmental screening tests are administered (see Chapter 6). Mental health status can influence activity level, physiologic parameters, and risk for certain conditions. Therefore, nurses should gather height and weight, review of systems, vital signs, and medication/substance use information. Family interactions, stressors, and methods of coping are assessed. When a potential mental health condition exists, the child receives further assessment from a mental health specialist. A resource commonly used is the *Diagnostic and Statistical Manual of Mental Disorders*, which lists diagnostic criteria for known mental health conditions. The current edition is the *DSM-5* (American Psychiatric Association, 2013).

Professionalism in Practice ***Diagnostic and Statistical Manual of Mental Disorders* (*DSM*)**

The *DSM-5* is the current compendium of psychiatric conditions, symptoms, and treatment. It includes screening tools and detailed information about pediatric mental health conditions such as attention deficit disorder, intellectual disability, and autism spectrum disorder. The pediatric nurse should access this information for screening tools and current evidence-based practice symptoms, and recognize the importance of acting as a person who identifies mental health disorders and refers children for appropriate care (American Psychiatric Association, 2013; Selekman & Diefenbeck, 2014).

The primary treatment goal for children and adolescents with psychosocial disorders is to assist the child and family to achieve and maintain an optimal level of functioning through interventions designed to reduce the impact of stressors. Therapeutic interventions and communication are based on the principle that feelings motivate behaviors. Parents and others close to the child often fall into the habit of reacting to the child's behaviors rather than trying to find out what feelings may be precipitating the undesirable actions. While behaviors may be considered in treatment, feelings and life experiences are often explored to provide insight and lead to behavior change. Medication may be used to enhance and support other therapy, or it may be the major therapeutic measure.

TREATMENT MODES

Three basic treatment modes are used: individual, family, and group therapy. The choice of treatment mode must take into account the child's age and developmental stage. Most therapists use several intervention strategies simultaneously. Different strategies are more or less effective and appropriate for children and adolescents in various stages of development. A thorough understanding of developmental needs, expectations, and abilities is therefore essential for mental healthcare providers.

Individual Therapy. Individual therapy involves only the child and the therapist. Treatment of specific emotional problems or disorders may involve various techniques such as play therapy, **psychodrama** (being assigned and playing out roles spontaneously in a therapeutic setting to assist in better understanding of the dynamics of a situation), art therapy, and **cognitive therapy** (a technique used to help a person recognize automatic negative thinking). Individual therapy may be short term (four to six sessions) or long term (lasting for several years).

Family Therapy. Family therapy involves the exploration of a particular emotional problem and its manifestations among the family members. Family therapy is based on the idea that the emotional symptoms or problems of an individual are an expression of emotional symptoms or problems in the family. The focus is on the relationships among the family members, not the psychologic conflict within each individual member.

Group Therapy. Group therapy involves an ongoing or limited number of sessions in which several individuals participate. The emphasis is on the interpersonal styles of relating to one another in the group. Group therapy is particularly effective with adolescents because of the importance of the peer group at this age. An advantage of group therapy is that stimuli and feedback come from multiple sources (the group members) instead of just one person (the therapist).

THERAPEUTIC STRATEGIES

Play Therapy. Play is often called the language or work of the child. From a developmental perspective, children progressively learn to express feelings and needs through action, fantasy, and finally language. The special quality of play buffers children against the pressures and demands of daily life. Play helps children master developmental stages by strengthening physical and neurologic processes. Play also assists in cognitive learning, setting the stage for problem solving and creativity.

Play therapy is a technique that reveals problems on a fantasy level through the use of toys, dolls, clay, art, and other creative objects. It is often used with preschool and school-age children who are experiencing anxiety, stress, and other specific nonpsychotic mental disorders. Play therapy encourages children to act out feelings such as anger, hostility, sadness, and fear. It also gives the therapist a chance to help children understand, on a conscious or unconscious level, their own responses and behavior in a safe, supportive environment. This type of therapy was used for Cassandra, described in the chapter-opening quotation, who needed to gain some control over a frightening environment by acting out fears and trying solutions during play with a therapist. Play therapy is different from therapeutic play, which may be used with hospitalized children (see Chapter 11). Only a specialist is qualified to provide play therapy for mental health disorders.

Art Therapy. Children who may be apprehensive about playing can sometimes be encouraged to participate in art therapy, using brief drawing exercises. This technique is appropriate for children of all ages, including adolescents. The drawings can help the therapist gain information about the child, the family, and the interactions between the child and family. However, children's drawings should never be the only basis for a definitive diagnosis.

When used in conjunction with a thorough history and appropriate psychologic testing information, art therapy can guide the child's treatment. These drawing exercises provide an opportunity to help in the healing process. The therapist can assist the child to release feelings of anger, pain, or fear onto paper, where they can be examined objectively. (Figures 28–1 to 28–4 present several examples of this technique.)

Figure 28–1 "Me." Drawn by a 14-year-old girl with major depression, anxiety, and school phobia who had experienced multiple losses over several years. Her mother had severe chronic lung problems and diabetes, and the girl had stopped attending school for fear that something would happen to her mother. This drawing represents the girl's obvious feelings of sadness and depression but also indicates a glimmer of hope (represented by the yellow mask coming from behind the dark mask of depression).

Figure 28–2 "Self-Portrait." Drawn by a 15-year-old boy who was admitted through the emergency department after a failed suicide attempt by hanging. He had a psychiatric diagnosis of depression and polysubstance abuse (including inhalants and alcohol), and he insisted that he was a member of a satanic cult in his hometown. Most of his drawings depicted a preoccupation with violence and suicide. The boy said that he always felt a "darkness" like a shadow that followed him around and wanted him dead. His family history was significant for depression and suicide on both his mother's and his father's side. His father also had a lengthy history of polysubstance abuse and alcoholism. The boy was discharged to a long-term residential treatment facility for adolescents.

Figure 28–3 "An Activity." Drawn by an 8-year-old boy who was initially admitted to the medical–surgical floor of a pediatric hospital for dehydration resulting from vomiting and diarrhea. Psychiatric evaluation was ordered for extreme anxiety. These drawings, completed during the initial interview, led to further investigation, which revealed that the child had started a house fire in which his grandmother (his primary caretaker at the time) was killed. The family's home and all their belongings were lost. No one had known that the child had set the fire. Further sessions indicated that he had been setting neighborhood garage fires and watching them burn from a distance.

Figure 28–4 "A Family Activity." By the same boy who drew Figure 28–3. This drawing depicts a recurring incident of physical and emotional abuse by his mother's live-in boyfriend. It shows the family bathtub with feces and blood smeared on the floors and walls. The boy reported that when either he or his 3-year-old brother had a toileting accident the boyfriend would make them go into the bathroom and stand in the bathtub while he smeared the feces on the walls. He would then hit the children and make them clean up the mess. The boy had previously been removed from the mother's custody for neglect. He was transferred from the medical–surgical area to the inpatient children's psychiatric unit, where he received a diagnosis of depression, overanxious disorder, and child abuse (physical and emotional). Charges were filed against the mother's boyfriend and custody of both children was temporarily revoked.

Cognitive and Behavioral Therapy (CBT). A combination of cognitive and behavioral therapy is useful in treating many mental health conditions in children. Cognitive therapy teaches thinking patterns to change reactions to situations that cause anxiety or other undesirable conditions. Children are taught how their brain and body are working; this understanding assists them in having control over the experience and responding with appropriate behaviors (Mayo Clinic, 2013a).

Behavior modification is a therapeutic technique that uses stimulus and response conditioning to alter inappropriate behaviors. It reinforces desirable behaviors, helping the child to replace maladaptive behaviors with more appropriate ones. This technique is based on the assumption that any learned behavior can be unlearned. Thus, if parents, nurses, teachers, and other adults consistently reinforce desirable behaviors, the child will eventually alter or discontinue undesirable behaviors.

Behavior modification may include (1) removing the child from the home to a more structured environment, such as a hospital, for a brief time, and (2) teaching the parents, teachers, and other appropriate adults to be agents of behavioral change. Several ongoing sessions may be required with the adults involved, using role playing and other techniques. Consistency is the most important principle in the success of behavior modification.

Visualization and Guided Imagery. The techniques of visualization and guided imagery begin with specific directions for progressive relaxation according to the child's ability. This form of therapy uses the child's own imagination and positive thinking to reduce stress and anxiety, decrease the experience of pain or discomfort, and promote healing. The techniques are especially useful for managing anxiety disorders and chronic pain. It is not easy for all children to use their imagination in this way, so the technique may not work or be appropriate for everyone.

Hypnosis. Hypnosis involves varying degrees of suggestibility and deep relaxation effects. This technique is useful for children and adolescents because they can usually be hypnotized more easily than adults. Hypnosis is especially helpful in treating physical symptoms with a psychologic component, anxiety, and phobias. It is also useful in managing severe physical symptoms or discomfort (pain or nausea) associated with a physiologic disorder or its treatment (e.g., cancer or juvenile rheumatoid arthritis).

Nursing Management

Ongoing assessment of all children and their families for mental health risk should be performed from the beginning of life and throughout childhood and adolescence. When a potential mental health condition exists, the child should receive further assessment from a mental health specialist. Nursing assessment focuses on child behaviors, family interactions, lifestyle routines, developmental progression, and treatment for mental health or cognitive conditions (see *Assessment Guide: The Child With an Alteration in Mental Health or Cognition* earlier in this chapter).

Many mental health disorders are managed effectively with therapy, medication, or both on an outpatient basis, whereas some necessitate admission to an inpatient psychiatric setting. Therefore, the nurse may encounter the child with a mental health disorder in a variety of community settings or during hospitalization for a concurrent psychiatric or physiologic problem.

EVIDENCE-BASED PRACTICE | Pharmacogenetics and the Nursing Role

Clinical Question

Great variability is seen in the response to psychotropic medicines used to treat mental health disorders such as depression. Children and adolescents show even more variability than adults, related to developmental variation in absorption, distribution, metabolism, and elimination; therefore, close monitoring is essential (Madadi, 2015). How can the nurse apply new technologies about individualized treatments to medications when providing mental health care for youth?

The Evidence

The fields of genetics and genomics are growing rapidly (see Chapter 3). Currently, pharmacogenetic testing is being used so that clinicians can select the best psychotropic medications for particular clients. For example, a genetic test for a gene that codes for high manufacture of a body enzyme that metabolizes a particular medication predicts that the client will not respond well to that medication. Another psychotropic can be chosen to enhance response. On the other hand, if the client is a slow metabolizer of the medication, an increased risk of toxicity results. A tailored approach to treatment of attention deficit hyperactivity disorder (ADHD) has the potential to target specific gene patterns rather than using a trial-and-error approach to types of medications tried (Bruxel et al., 2014). Community treatment of mental health disorders has the potential to be enhanced by identification of the best drug to treat a given person. Nurses are called on to collect genetic samples (often from inside the mouth) and explain the procedure and results to families (Bartlett, 2011; Haga, O'Daniel, Tindall, et al., 2012). These roles demand that nurses understand genomics and pharmacogenetics in order to translate concepts to families (Knisely, Carpenter, & Von Ah, 2014).

Best Practice

The nurse in a setting where children and adolescents are treated for psychiatric disorders has an important role in applying new knowledge related to pharmacogenetics. First, the nurse needs to take a careful history of medications, over-the-counter products, and herbal remedies because many of these substances compete with psychotropic medications for metabolism in the body. When a DNA test is recommended prior to beginning medication, families need to understand the reason for the test. They will also need explanations about the test results and how they relate to the specific medication that has been prescribed. It is important that all children and adolescents receiving psychotropic medications be closely monitored for responses and side effects. The nurse is integral to the ongoing evaluation of the prescribed therapy (Kniseley et al., 2014).

Clinical Reasoning

What is the nursing role in history taking and in monitoring for the child or adolescent on psychotropic medication? What questions do you think a family is likely to ask when they learn that a genetic test is recommended before prescribing medication to an adolescent experiencing a mental health disruption such as severe depression? Where will you find the information about pharmacogenetics and pharmacogenomics that will provide necessary background for you and the family? How can pharmacogenetic testing enhance the treatment of individuals by both leading to a therapeutic response in a short time and avoiding serious side effects?

In the hospital, nursing care includes carrying out the prescribed treatment plan and administering psychotropic medications. Evaluate the child's medication regimen for administration schedule, dosage, side effects, and effectiveness. See accompanying *Evidence-Based Practice: Pharmacogenetics and the Nursing Role.*

An important nursing intervention is to ensure safety of the child. Actions begin in the emergency department if a child is admitted for a mental health crisis. Remove or lock up potentially dangerous material such as medications, tubing, and sharps containers that may be in the child's room. A parent, guardian, or healthcare provider should remain with the child at all times. Inform the family member of the need to stay with the child and how to immediately notify the nurse if the adult needs to leave or if the child's condition changes. Part of the initial care is to evaluate risk by asking if the child has tried to hurt himself/herself or has been thinking about it. Ask about recent stresses, thoughts of hurting someone else, and why the child thinks she/he has been brought to the emergency department. If the child is admitted to the psychiatric unit, follow unit policies for ensuring safety for children who are at risk of hurting themselves or others.

Developing Cultural Competence **Spiritual Beliefs and Mental Health**

In many cultures, care of the "spirit" is believed necessary to promote mental health. An identity with one's community and spiritual wholeness is promoted by storytelling, singing, rites of passage, and use of certain objects such as bags of herbs. Use of healers, family and community support, relaxation or meditation, exorcism, or other procedures may be used by families. Ask what the family believes about mental health, and integrate safe and culturally acceptable practices into the plan of care to enhance the child's mental health.

Psychiatric hospitalization is a stressful event for all families, and both the family and child need supportive care. Continuation of family involvement is critical. The nurse frequently is the liaison between the family and the therapist in making follow-up arrangements at the time of discharge. Be aware of the meaning of mental illness in various cultural groups and the treatments that may be commonly used. Integrate these complementary therapies into the care plan whenever safe. Families must feel that their responses and approaches to the child with a mental disorder are not judged by healthcare providers.

The nurse in the community assesses how a child with a mental health disorder is functioning in each microsystem, such as home, day care, school, and with friends. Assess risk and protective factors of the child and family (see Chapter 4). Evaluate involvement in therapy sessions and ability to manage prescribed pharmacologic interventions.

Developmental and Behavioral Disorders

Autism Spectrum Disorder (Neurodevelopmental Disorder)

An estimated 12% to 16% of children have a developmental or behavioral disorder. The most common group of disorders is called *autism spectrum disorder (ASD)*, which affects about 14.7/1000 children (Centers for Disease Control and Prevention [CDC], 2012a, 2014a). This neurodevelopmental disorder begins in early childhood and is characterized by impaired social interactions and communication, with restricted interests, activities, and behaviors, and repetitive patterns of behavior (American Psychiatric Association, 2013). ASD may be accompanied by other neurodevelopmental, mental, or behavioral conditions, so the manifestations can differ significantly among individuals. ASD is comprised of autism, Asperger syndrome, pervasive developmental disorder not otherwise specified, Rett syndrome, and childhood disintegrative disorder. The present incidence of ASD represents an increase from formerly described levels; before 1985, less than 1 child in 1000 was diagnosed with an autistic disorder. It is unclear whether there is a true increase in cases or simply improved techniques in making the diagnosis, as well as an enlarged diagnostic category that includes more children. The disorder is more common in males than females; peak age at diagnosis is 8 years, but symptoms often begin by 12 to 24 months of age (CDC, 2012a, 2014a).

ETIOLOGY AND PATHOPHYSIOLOGY

The etiology of autism spectrum disorder is unknown. Genes are clearly involved, although a complex array of genes appears to be responsible (Frye, 2014). Immune responses, environmental exposures, certain drugs during pregnancy, and neuroanatomy are being investigated as influences that interact with genetics to cause ASDs (CDC, 2014a; Won, Mah, & Kim, 2013). Neurotransmitters such as dopamine, serotonin, and opioids are abnormal in some children and are a focus of research. Fetal alcohol syndrome, fragile X syndrome, phenylketonuria, Down syndrome, and tuberous sclerosis are all associated with a higher than normal incidence of autism (Won et al., 2013). Despite concern expressed in earlier medical and lay press, no demonstrated relationship has been demonstrated between the measles-mumps-rubella vaccine or thimerosal (mercury-based preservative in some vaccines) and the incidence of ASDs (see Chapter 16 for further information on immunizations) (Maglione et al., 2014).

CLINICAL MANIFESTATIONS

The essential features of autism spectrum disorder typically become apparent by the time a child is 3 years of age. They involve impairments in socialization, communication, and behavior (Harrington, 2013; Webb, 2011). Children with ASD are unable to relate to people in a manner that is common for young children, or to respond to social and emotional cues. In addition, they may engage in **stereotypy**, or rigid, repetitive, and machine-like movement with obsessive behavior (Figure 28–5). Characteristically, these repetitive behaviors in affected children include head banging, twirling in circles, biting themselves, and flapping their hands or arms. Frequently, a child's behavior is self-stimulating or self-destructive. Responses to sensory stimuli are frequently abnormal and include an extreme aversion to touch, loud noises, and bright lights. Emotional lability is common.

Communication difficulties or delays in speech and language are common, and are often the first symptoms that lead to diagnosis. Abnormal communication patterns include both verbal and nonverbal communication. Absence of babbling and other communication by age 1 year, absence of two-word phrases by age 2 years, and deterioration of previous language skills are characteristic. Children with ASD may eventually learn to talk, in some cases well, but their speech is likely to show certain abnormalities: use of *you* in place of *I;* **echolalia** (a compulsive parroting of what is heard); repeating questions rather than answering them; and fascination with rhythmic, repetitive songs and verses.

Figure 28–5 Stereotypy. This child with ASD sits stiffly in the chair and engages in rhythmic rocking behavior. He has a disengaged look and does not readily interact with other children or adults who are in his environment.

Behaviors of children with ASD show several differences from other children. They do not commonly explore objects but display stereotypy. They may line up objects, play with the same objects over and over, and have certain rituals that must be performed. They often become upset if these normal routines are disrupted. Rituals may involve eating only certain types or colors of foods or eating in specific patterns. Children may manifest disturbances in the rate or sequence of development. They frequently have cognitive impairment but can demonstrate a wide range of intellectual ability and functioning. Cognitive impairment may manifest early in life as slow developmental progression, particularly in social skills. Some children are impaired in particular areas of development, whereas others are above normal.

The clinical manifestations common in autistic spectrum disorder are listed in Table 28–1.

CLINICAL THERAPY

The first step in identifying children at risk of ASD is surveillance at each healthcare visit. Since diagnosis and treatment have often been delayed, the American Academy of Pediatrics has now identified a multistage process for surveillance and screening:

1. Perform surveillance at early healthcare visits to identify if a sibling has ASD, parents or other caregivers are concerned about the developmental progression of the child, or the healthcare provider notes abnormalities in child behavior.
2. The healthcare provider determines if the child appears to be at risk for ASD.
3. The healthcare provider evaluates the risks. If risk exists, the provider administers an age-appropriate and ASD-specific screening tool (e.g., Ages and Stages Questionnaire and Modified Checklist for Autism in Toddlers [M-CHAT]).
4. If no risk exists, an ASD-specific tool is administered at the 18- and 24-month visits.
5. Select appropriate screening tool for age and risk profile of the child.
6. If screening is negative for a child with some risk, provide information to parents and evaluate again in 1 month. If screening is positive, refer for comprehensive ASD evaluation, including audiology, and begin early intervention programs (Harrington, 2013; Johnson et al., 2007, reaffirmed, 2010; Webb, 2011).

Several screening tests are available for use in health maintenance visits if autistic disorder is suspected. Additional testing is performed to rule out other causes of the child's behavior. Tests may include neuroimaging (CT scan or MRI), lead screening,

TABLE 28–1 Clinical Manifestations of Autism Spectrum Disorder

CLINICAL MANIFESTATIONS	CLINICAL THERAPY
Impaired social, communicative, and behavioral development, usually noted in first year of life.	Early intervention is key to maximal performance. Interventions focus on improving behaviors and communication skills, providing physical and occupational therapy, structuring play interactions with other children, and educating parents about the child's needs.
Impaired social interactions with normal language development for age; pitch, tone, and other speech characteristics may be abnormal. Verbal skills involving spelling and vocabulary are high but concept formation, language flexibility, and comprehension are low. Intellectual functioning may be at a high level, particularly in certain areas, whereas social skills are limited.	Social interactions are focus of therapy.
Early development often appears normal, but symptoms emerge at 6–18 months. Ataxia, handwringing, intermittent hyperventilation, dementia, and growth retardation show progressive increase. Appears only in females as an X-linked dominant disorder; mutations occur in the *MeCP2* gene, affecting methyl-CpG–binding protein 2, which is important in brain development.	Early intervention in areas of abnormal behaviors.
First 2–5 years of development appear normal followed by deterioration in many areas of functioning. Behaviors finally stabilize at some point without further deterioration.	Focus on areas of developmental function that show abnormality. Individualized education plans are needed in school to deal with communication, play, physical therapy, and teaching management skills to parents. Regression in toileting and other skills may occur.
Severe social impairment without meeting *DSM* criteria for other types of autistic spectrum disorder.	Behavioral therapy focuses on building social skills.

metabolic studies, DNA analysis, and electroencephalogram. See Chapters 5 and 27 for further descriptions related to neurologic system assessment. Diagnosis is based on the presence of specific criteria, as described in the American Psychiatric Association's *DSM-5* (see Table 28–2).

Early intervention helps maximize the child's potential by improving developmental skills and behaviors, as well as establishing helpful support for parents. Treatment focuses on behavior management to reward appropriate behaviors (called *applied behavior analysis [ABA]*), foster positive or adaptive coping skills, and facilitate effective communication. The goals of treatment are to reduce rigidity or stereotypy and other maladaptive behaviors. Some children must be physically restrained from aggressive or self-destructive behaviors. Speech therapy is an essential part of treatment. Instruction in social skills and occupational therapy to improve fine motor dexterity and sensory integration are provided. Some parents choose to use complementary therapies.

The overall prognosis for children with ASD to become functioning members of society varies. Successful adjustment is more likely for children with higher IQs, adequate speech, and access to specialized programs.

Nursing Management

For the Child With ASD or Neurodevelopmental Disorder

Nursing Assessment and Diagnosis

The nurse may encounter the child with ASD during routine well-child visits, or when parents seek care for a suspected hearing impairment, speech difficulty, or developmental delay. Early and frequent developmental screening of all children can help in referral for thorough assessment and identification of cases. Be alert to parental observations that the baby or young child does

TABLE 28–2 *DSM-5* Diagnostic Criteria for Autistic Spectrum Disorder

1. Persistent deficits in social communication and social interaction across multiple contexts, as manifested by the following, currently or by history (examples are illustrative, not exhaustive):
   - Deficits in social-emotional reciprocity, ranging, for example, from abnormal social approach and failure of normal back-and-forth conversation; to reduced sharing of interests, emotions, or affect; to failure to initiate or respond to social interactions.
   - Deficits in nonverbal communicative behaviors used for social interaction, ranging, for example, from poorly integrated verbal and nonverbal communication; to abnormalities in eye contact and body language or deficits in understanding and use of gestures; to a total lack of facial expressions and nonverbal communication.
   - Deficits in developing, maintaining, and understanding relationships, ranging, for example, from difficulties adjusting behavior to suit various social contexts; to difficulties in sharing imaginative play or in making friends; to absence of interest in peers.

   Specify current severity:

   - Severity is based on social communication impairments and restricted, repetitive patterns of behavior.
2. Restricted, repetitive patterns of behavior, interests, or activities, as manifested by at least two of the following, currently or by history (examples are illustrative, not exhaustive; see text):
   - Stereotyped or repetitive motor movements, use of objects, or speech (e.g., simple motor stereotypies, lining up toys or flipping objects, echolalia, idiosyncratic phrases).
   - Insistence on sameness, inflexible adherence to routines, or ritualized patterns of verbal or nonverbal behavior (e.g., extreme distress at small changes, difficulties with transitions, rigid thinking patterns, greeting rituals, need to take same route or eat same food every day).
   - Highly restricted, fixated interests that are abnormal in intensity or focus (e.g., strong attachment to or preoccupation with unusual objects, excessively circumscribed or perseverative interests).
   - Hyper- or hyporeactivity to sensory input or unusual interest in sensory aspects of the environment (e.g., apparent indifference to pain/temperature, adverse response to specific sounds or textures, excessive smelling or touching of objects, visual fascination with lights or movement).

   Specify current severity:

   - Severity is based on social communication impairments and restricted, repetitive patterns of behavior.
3. Symptoms must be present in the early developmental period (but may not become fully manifest until social demands exceed limited capacities, or may be masked by learned strategies in later life).
4. Symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning.
5. These disturbances are not better explained by intellectual disability (intellectual developmental disorder) or global developmental delay. Intellectual disability and autism spectrum disorder frequently co-occur; to make comorbid diagnoses of autism spectrum disorder and intellectual disability, social communication should be below that expected for general developmental level.

Note: Individuals with a well-established *DSM-IV* diagnosis of autistic disorder, Asperger's disorder, or pervasive developmental disorder not otherwise specified should be given the diagnosis of autism spectrum disorder. Individuals who have marked deficits in social communication, but whose symptoms do not otherwise meet criteria for autism spectrum disorder, should be evaluated for social (pragmatic) communication disorder.

Specify if:

- With or without accompanying intellectual impairment
- With or without accompanying language impairment
- Associated with a known medical or genetic condition or environmental factor
- Associated with another neurodevelopmental, mental, or behavioral disorder

not look at them or provides other developmental or behavioral cues. Parents may report abnormal interaction such as lack of eye contact, disinterest in cuddling, minimal facial responsiveness, and failure to talk. Be alert for the "red flags": no babbling or communication gestures by 12 months, no single word by 16 months, no spontaneous two-word phrases by 24 months, or loss of language or social skills previously achieved (Johnson et al., 2007, reaffirmed 2010).

Assessment at every healthcare visit focuses on language development, response to others, and hearing acuity (see Chapters 4 and 5). Specialized screening tests for ASD may be administered. Pediatric nurses in outpatient settings should ensure that a variety of autism screening tools for different ages of children are available and used in healthcare settings (Webb, 2011).

When a child with a diagnosis of autistic disorder is hospitalized for a concurrent problem, obtain a history from the parents about the child's routines, rituals, and likes and dislikes, as well as ways to promote interaction and cooperation. Children with ASD may carry a special toy or object that they play with during times of stress. Ask parents about these objects and their use. Document this information in the clinical record.

Ask about the child's behaviors and observe them on admission. Obtain a history of acute and chronic illnesses and injuries. Ask about eating patterns and food restrictions. Inquire about complementary and alternative medicine treatments in a nonjudgmental and supportive manner.

Nursing diagnoses must be tailored to fit the individual needs of the child. Examples of nursing diagnoses that might be appropriate for children with ASD include the following (NANDA-I © 2014):

- ***Communication: Verbal, Impaired,*** related to psychologic condition
- ***Social Interaction, Impaired,*** related to developmental disability
- ***Injury, Risk for,*** related to cognitive impairment
- ***Caregiver Role Strain, Risk for,*** related to chronicity and demands of child's condition
- ***Coping: Family, Compromised,*** related to having a child with prolonged disability

Planning and Implementation

Nursing care focuses on stabilizing environmental stimuli, providing supportive care, enhancing communication, maintaining a safe environment, giving the parents anticipatory guidance, and providing community-based care.

STABILIZE ENVIRONMENTAL STIMULI

Children with ASD interpret and respond to the environment differently from other individuals. Sounds that are not distressing to the average person may be interpreted by children with ASD as louder, more frightening, and overwhelming. The child needs to be oriented to new settings such as a classroom or the hospital room, and may adjust best to a small classroom or to a hospital room with only one other child. Encourage parents to bring the child's favorite objects from home, and try to keep these objects in the same places because the child does not cope well with changes in the environment.

PROVIDE SUPPORTIVE CARE

Developing a trusting relationship with the child with ASD is often difficult. Adjust communication techniques and teaching to the child's developmental level. Ask parents about the child's usual home routines, and maintain these routines as much as possible when the child is out of the home. Because self-care abilities are often limited, the child may need help meeting basic needs. School programs and individualized education plans (IEPs) (see Chapter 12) can help the child learn self-care skills. When possible, schedule daily care and routine procedures at consistent times to maintain predictability. Encourage parents to remain with the hospitalized child and to participate in daily care planning. Parents are integral parts of the treatment team when the child's learning goals are established in early intervention or school programs. Identify rituals for naptime and bedtime, and maintain them to promote rest and sleep. Establish patterns that help the child eat nutritious foods at mealtimes.

Use of complementary medicine for children with autistic spectrum disorder is common. Parents choose modalities such as special diets, use of supplements and vitamins, herbs, auditory training, hyperbaric treatment, chiropractic manipulation, and nonprescription medications such as melatonin (Valicenti-McDermott et al., 2014). Nurses should inquire about use of complementary therapies and provide information for the family to ensure safe practices.

ENHANCE COMMUNICATION

Since children with ASD have impaired communication, nursing care focuses on using and improving communication with the child. Speech is used when possible; short, direct sentences are usually most effective. When the child responds well to visual cues, pictures, computers, and other visual aids may form an important part of interactions. Some children use sign language.

MAINTAIN A SAFE ENVIRONMENT

Monitor children with ASD at all times, including bath time and bedtime. Close supervision is needed to ensure that the child does not obtain any harmful objects or engage in dangerous behaviors. Bicycle helmets and mittens are sometimes used to protect children with ASD so that they can safely participate in activities.

PROVIDE ANTICIPATORY GUIDANCE

Approximately half of all children with autistic disorder require lifelong supervision and support. This is especially true if the disorder is accompanied by intellectual disability (mental retardation). Some children may grow up to lead independent lives, although they will have social limitations with impaired interpersonal relationships. Encourage parents to promote the child's development through behavior modification and specialized educational programs. The overall goal is to provide the child with the guidance, education, and support necessary for optimal functioning.

COMMUNITY-BASED NURSING CARE

Families need a great deal of support to cope with the challenges of caring for the child with ASD. The diagnosis may trigger feelings of grief and shock. Help the family identify resources for child care, such as special toddler programs, preschools, and parent support groups. The child will need an individualized education and health plan; the school nurse is instrumental in establishing these plans. The parent or primary caretaker often has a hard time getting respite care and may need assistance to find suitable resources. Siblings of the child with ASD may need help explaining the disorder to their friends or teachers. Family support programs are available in some states to provide assistance to parents.

Offer the family resources for genetic counseling. Parents need information about the need for immunizations since they may have heard erroneous information about a connection between immunization and the disorder. Encourage parents to

have the child immunized on the recommended schedule. Parents may have questions about where to find information on complementary and alternative therapies.

Local support groups for parents of children with ASD exist in most areas. Parents can also be referred to the Autism Society of America, the American Academy of Pediatrics, and the Centers for Disease Control and Prevention for information.

Evaluation

Expected outcomes of nursing care for the child with ASD include the following:

- Behavioral symptoms are effectively managed.
- The child performs elements of self-care.
- The child remains free from injury.
- Consistent developmental progression is observed.
- The child develops successful communication strategies.

Attention Deficit Disorder and Attention Deficit Hyperactivity Disorder

Attention deficit disorder (ADD) is a variation in central nervous system processing characterized by developmentally inappropriate behaviors involving inattention. When hyperactivity and impulsivity accompany inattention, the disorder is called *attention deficit hyperactivity disorder (ADHD)*. The latter is the more common condition and affects about 11% of school-age children; boys (13.2%) are affected more often than girls (5.6%) (CDC, 2014b). It is also known to affect adolescents and adults, and those with the disorder often continue to manifest at least some of the symptoms as they grow into adulthood. Hyperactivity and impulsivity may improve as the child nears adulthood, with inattentiveness being the most persistent characteristic.

ETIOLOGY AND PATHOPHYSIOLOGY

Although a variety of physical and neurologic disorders are associated with ADHD, children with identifiable causes represent a small proportion of this population. Examples of known associations include exposure to high levels of lead or mercury in childhood and prenatal exposure to alcohol or tobacco smoke. Other prenatal factors associated with a higher incidence of ADHD include preterm labor, impaired placenta functioning, and impaired oxygenation. Seizures and serious head injury are other potential associations. Genetic factors may be important, as well as family dynamics and environmental characteristics. Although ADHD occurs more commonly within families (25% have a first-degree relative with the disorder), a single gene has not been located and a specific mechanism of genetic transmission is not known. It is believed that a genetic predisposition interacts with the child's environment, so that both factors contribute to the appearance of the condition. Family stress, poverty, and poor nutrition may also be contributing factors. Although daily television exposure at ages 1 to 3 years has been associated with attention symptoms of the condition later in childhood, not all studies verify this finding (Ferguson, 2011; van Egmond-Frohlich, Weghuber, & de Zwaan, 2012). It is likely that there are many types of attention deficit, resulting from several different mechanisms that involve interaction of genetic, biologic, and environmental risk factors.

The pathophysiology of ADD/ADHD is not totally known. However, some children exhibit a deficit in the catecholamines dopamine and norepinephrine, lowering the threshold for stimuli input. The disorder is marked by brain maturation delay in the area of self-regulation. Increased input from stimuli and decreased self-regulation cause the hallmark inability to inhibit stimuli and motor activity. Slow brain maturity, in the first 3 years of life, has now been demonstrated on imaging studies. The cortex is particularly affected and may explain the school and concentration difficulty associated with the disorder (National Institutes of Health [NIH], 2012).

CLINICAL MANIFESTATIONS

Children with ADD and ADHD have problems related to decreased attention span, impulsiveness, or increased motor activity. Symptoms can range from mild to severe. The disorders often coexist with various developmental learning disabilities. The child has difficulty completing tasks, fidgets constantly, is frequently loud, and interrupts others. Sleep disturbances are common. Because of these behaviors, the child often has difficulty developing and maintaining social relationships and may be shunned or teased by other children. This only increases the anxiety of the already compromised child, whose behavior is set on a downward-spiraling course.

Typically, girls with ADHD show less aggression and impulsiveness than boys, but far more anxiety, mood swings, social withdrawal, rejection, and cognitive and language problems. Girls tend to be older at the time of diagnosis. Children are frequently diagnosed with the disorder soon after beginning school, with its demands for attentive behavior.

CLINICAL THERAPY

Children are usually brought for evaluation when behaviors escalate to the point of interfering with the daily functioning of teachers or parents. Any child from ages 4 through 18 years who has academic problems, behavior difficulties, inattention, hyperactivity, or impulsivity should be evaluated for ADHD (Subcommittee on Attention-Deficit/Hyperactivity Disorder [Subcommittee on ADHD], 2011). When children have learning disabilities or anxiety disorders, the problem is commonly misdiagnosed as ADHD if full and accurate evaluation of the child's symptoms is not performed. Obtaining an accurate diagnosis after comprehensive testing by a pediatric mental health specialist is vital (NIH, 2012). Specific diagnostic criteria must be applied to all children with the potential diagnosis (see *DSM-5* criteria in Table 28–3). The diagnosis of ADD is often difficult because of the absence of hyperactivity behaviors. Behaviors at home, school, or childcare centers must be evaluated because abnormal patterns in two settings are needed for diagnosis. A variety of tests are available for use by the trained professional in establishing the diagnosis.

Diagnosis begins with a careful history of the child, including family history, birth history, growth and developmental milestones, behaviors such as sleeping and eating patterns, progression and patterns in school, social and environmental conditions, reports from parents and teachers, and any other emotional or behavioral condition (Subcommittee on ADHD, 2011). A physical examination should be performed to rule out neurologic diseases and other health problems. The mental health specialist then performs testing of the child and administers questionnaires to the parent and teacher. It is important to identify other conditions that may either mimic ADD/ADHD or exist in conjunction with the disorders. These might include depression, anxiety, learning disorder, conduct disorder, or oppositional defiant disorder.

Treatment is established to meet the desired behavioral outcomes, and includes a combination of approaches, such as environmental changes, behavior therapy, and pharmacotherapy. The condition is chronic, so assessment should be ongoing for follow-up and evaluation of other mental health conditions (Brown, 2012).

TABLE 28–3 *DSM-5* Diagnostic Criteria for Attention Deficit Hyperactivity Disorder

A. A persistent pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development, as characterized by 1 and/or 2:
   1. *Inattention:* Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities:
      a. **Note:** The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.
      b. Often fails to give close attention to details or makes careless mistakes in schoolwork, at work, or during other activities (e.g., overlooks or misses details, work is inaccurate).
      c. Often has difficulty sustaining attention in tasks or play activities (e.g., has difficulty remaining focused during lectures, conversations, or lengthy reading).
      d. Often does not seem to listen when spoken to directly (e.g., mind seems elsewhere, even in the absence of any obvious distraction).
      e. Often does not follow through on instructions and fails to finish schoolwork, chores, or duties in the workplace (e.g., starts tasks but quickly loses focus and is easily sidetracked).
      f. Often has difficulty organizing tasks and activities (e.g., difficulty managing sequential tasks; difficulty keeping materials and belongings in order; messy, disorganized work; has poor time management; fails to meet deadlines).
      g. Often avoids, dislikes, or is reluctant to engage in tasks that require sustained mental effort (e.g., schoolwork or homework; for older adolescents and adults, preparing reports, completing forms, reviewing lengthy papers).
      h. Often loses things necessary for tasks or activities (e.g., school materials, pencils, books, tools, wallets, keys, paperwork, eyeglasses, mobile telephones).
      i. Is often easily distracted by extraneous stimuli (for older adolescents and adults, may include unrelated thoughts).
      j. Is often forgetful in daily activities (e.g., doing chores, running errands; for older adolescents and adults, returning calls, paying bills, keeping appointments).

   2. *Hyperactivity and impulsivity:* Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities:
      a. **Note:** The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or a failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.
      b. Often fidgets with or taps hands or feet or squirms in seat.
      c. Often leaves seat in situations when remaining seated is expected (e.g., leaves his or her place in the classroom, in the office or other workplace, or in other situations that require remaining in place).
      d. Often runs about or climbs in situations where it is inappropriate. (**Note:** In adolescents or adults, may be limited to feeling restless.)
      e. Often unable to play or engage in leisure activities quietly.
      f. Is often "on the go," acting as if "driven by a motor" (e.g., is unable to be or uncomfortable being still for extended time, as in restaurants, meetings; may be experienced by others as being restless or difficult to keep up with).
      g. Often talks excessively.
      h. Often blurts out an answer before a question has been completed (e.g., completes people's sentences; cannot wait for turn in conversation).
      i. Often has difficulty waiting his or her turn (e.g., while waiting in line).
      j. Often interrupts or intrudes on others (e.g., butts into conversations, games, or activities; may start using other people's things without asking or receiving permission; for adolescents and adults, may intrude into or take over what others are doing).

B. Several inattentive or hyperactive-impulsive symptoms were present prior to age 12 years.

C. Several inattentive or hyperactive-impulsive symptoms are present in two or more settings (e.g., at home, school, or work; with friends or relatives; in other activities).

D. There is clear evidence that the symptoms interfere with, or reduce the quality of, social, academic, or occupational functioning.

E. The symptoms do not occur exclusively during the course of schizophrenia or another psychotic disorder and are not better explained by another mental disorder (e.g., mood disorder, anxiety disorder, dissociative disorder, personality disorder, substance intoxication or withdrawal).

Specify whether:

- **Combined presentation:** If both Criterion A1 (inattention) and Criterion A2 (hyperactivity-impulsivity) are met for the past 6 months.
- **Predominantly inattentive presentation:** If Criterion A1 (inattention) is met but Criterion A2 (hyperactivity-impulsivity) is not met for the past 6 months.
- **Predominantly hyperactive/impulsive presentation:** If Criterion A2 (hyperactivity-impulsivity) is met and Criterion A1 (inattention) is not met for the past 6 months.

Specify if:

- **In partial remission:** When full criteria were previously met, fewer than the full criteria have been met for the past 6 months, and the symptoms still result in impairment in social, academic, or occupational functioning.

Specify current severity:

- **Mild:** Few, if any, symptoms in excess of those required to make the diagnosis are present, and symptoms result in no more than minor impairments in social or occupational functioning.
- **Moderate:** Symptoms or functional impairment between "mild" and "severe" are present.
- **Severe:** Many symptoms in excess of those required to make the diagnosis, or several symptoms that are particularly severe, are present, or the symptoms result in marked impairment in social or occupational functioning.

Children often benefit from environmental changes. Decreasing stimulation—for example, by turning off television, keeping the environment quiet, and maintaining an orderly and clutter-free desk or study area without distraction—may help the child to stay focused on the task at hand. Another relatively simple change is appropriate classroom placement, preferably in a small class with a teacher who can provide close supervision and a structured daily routine. Consistent limits and expectations should be set for the child. Children living in chaotic homes and communities may function better if the environment can be simplified. When aggressive behaviors occur, therapeutic approaches such as play and group therapy may be useful.

Behavior therapy involves rewarding the child for desired behaviors and applying consequences for undesirable behaviors. Children may be rewarded by praise or earn points toward a movie or other desired outing for staying seated during meals or quietly listening in a classroom. All adults who are in close contact with the child, such as parents and teachers, must be educated to carry out the behavioral program (Subcommittee on ADHD, 2011).

Children with moderate to severe ADHD are treated with pharmacotherapy. Methylphenidate (Ritalin, Concerta) is most often prescribed, with alternatives of dextroamphetamine (Dexedrine or Adderall) and the nonstimulant medication atomoxetine. A skin patch that releases medication transdermally over a 9-hour period is available, facilitating ease of administration; a long-acting liquid medication formulation is also available (Findling & Dinh, 2014). Usually, a favorable response (a decrease in impulsive behaviors and an increase in the ability to sit still and attend to an activity for at least 15 minutes) is seen in the first 10 days of treatment and frequently with the first few doses. Guidelines recommend thorough evaluation of children before stimulant or other medication is prescribed in order to rule out any cardiac condition that could be affected by medication use.

A variety of complementary approaches, in addition to or instead of traditional behavioral therapy and medication, have been tried in children with ADD or ADHD. Chiropractic manipulation, biofeedback, yoga, massage, visual or auditory therapy, and dietary interventions have been used. Dietary therapies include elimination of dietary components such as highly processed foods, sugar, aspartame, or yeast and use of supplements such as omega-3 fatty acids, iron, magnesium, zinc, vitamin B_6, and herbs such as Pycnogenol (pine bark extract), melatonin, *Echinacea*, St. John's wort, and ginkgo biloba. Ask parents about alternative therapies used and investigate what is known about them in order to share this information with parents (Arnold, Hurt, & Lofthouse, 2013; Faraone & Antshel, 2014; Kemper, Gardiner, & Birdee, 2013).

Although ADHD was once thought to be a disorder of childhood that gradually improved with age, it is now known that ADHD is a chronic condition requiring ongoing management; for many individuals, symptoms continue into adulthood (American Psychiatric Association, 2013).

Nursing Management

For the Child With ADD or ADHD

Nursing Assessment and Diagnosis

The nurse often encounters the family who is concerned about the child's behavior before a diagnosis has been made. Ask about family and birth history and have the parents describe the child's behaviors. Perform developmental testing and look specifically for attention span and physical activity. Refer the family to their pediatric healthcare home for further assessment, and then to a mental healthcare specialist who is experienced in diagnosing ADHD. Schedule a visit for complete client and family history, physical examination, and electrocardiogram before medication is begun.

Nurses may encounter the child with ADHD in the hospital when parents bring the child for treatment of an injury (e.g., fracture) or other problem. Explore the parents' report of the child's attention span in detail. Usually within a few minutes in an unstructured setting or waiting area, the child with ADHD becomes restless and searches for distraction. Gather information about the child's activity level and impulsiveness. Be alert for information that reveals a serious problem, such as hurting animals or other children. Find out about distractibility, attention deficit in activities of daily living, characteristic ways of reacting, and the extent of impulsiveness when the child is receiving medication. Find out how the family manages at home. Ask about a family history of the disorder, because that is a common finding among children with ADHD.

Examples of nursing diagnoses that might be appropriate for a child with ADHD include the following (NANDA-I © 2014):

- ***Communication: Verbal, Impaired,*** related to altered perceptions
- ***Social Interaction, Impaired,*** related to chronic episodes of impulsive behavior
- ***Self-Esteem, Chronic Low,*** related to behaviors associated with ADD/ADHD
- ***Injury, Risk for,*** related to high level of impulsiveness and excitability
- ***Caregiver Role Strain, Risk for,*** related to management of child with unpredictable moods and high energy

Planning and Implementation

Prevention can focus on discouraging regular television exposure for young children from 1 to 3 years and encouraging daily vigorous physical activity for all children. Nursing care of the hospitalized child with ADD/ADHD focuses on administering medications, minimizing environmental distractions, implementing behavioral management plans, providing emotional support to the child and family, promoting self-esteem, and ensuring ongoing care.

ADMINISTER MEDICATIONS

Stimulant and nonstimulant medications increase the child's attention span and decrease distractibility. Be alert for the common side effects of these medications, including anorexia, insomnia, and tachycardia. Administering medication early in the day helps to alleviate insomnia. Anorexia can be managed by giving medication at mealtimes. Baseline cardiac examinations are needed, as well as periodic reevaluation. Careful monitoring of weight, height, and blood pressure is necessary. Instruct families about the abuse potential of stimulant drugs and teach them to keep the medications locked and to administer them only as directed.

MINIMIZE ENVIRONMENTAL DISTRACTIONS

The child may need an environment with minimal distractions. When hospitalized, this may mean a room with only one other child. Keep potentially harmful equipment out of reach. Monitor and limit television and video game time. Use shades to darken the room at nap- or bedtime, and minimize noise. Teach parents to minimize distractions at home during periods when the child needs to concentrate, for example, when doing schoolwork. Visits

to areas such as shopping malls and playgrounds may need to be limited. Plenty of daily exercise and minimal use of television and video games may help the child concentrate when needed for school and other tasks.

IMPLEMENT BEHAVIORAL MANAGEMENT PLANS

Behavioral modification programs can help reduce specific impulsive behaviors. An example is setting up a reward program for the child who has taken medication as ordered or completed a homework assignment. The rewards may be daily as well as weekly or monthly, depending on the child's age. For example, one completed homework assignment might be rewarded with 30 minutes of basketball or a bike ride; assignments completed for a week might be rewarded with an activity of the child's choice on the weekend.

If punishment is necessary, the behavior should be corrected while simultaneously supporting the child as a person. Punishment is generally withdrawal of a privilege, and should follow the offense quickly, as the child may not otherwise connect the punishment with the behavior.

PROVIDE EMOTIONAL SUPPORT

Children with ADD or ADHD offer a special challenge to parents, teachers, and healthcare providers. Parents must cope simultaneously with managing the difficult needs and demands of a hard-to-handle child, obtaining appropriate evaluation and treatment, and understanding and accepting the diagnosis, even when the child exhibits different behaviors with different people. Family support is essential. Educate both the parents and the child about the importance of appropriate expectations and consequences of behaviors. Teach skills that will help as the child grows older: making lists of tasks to accomplish; having routines for eating, sleeping, recreation, and schoolwork; minimizing stimuli in the environment when completing work; and asking teachers and friends to identify when behavior is inappropriate.

PROMOTE SELF-ESTEEM

As the child grows, ask about school and friends in order to assess self-concept and self-esteem. Help the child understand the disorder at an appropriate developmental level, and facilitate a trusting relationship with healthcare providers. Assist the child with social skills through role-play, playing in small groups, and modeling. Promote the child's self-esteem by pointing out the positive aspects of behavior and treating instances of negative behavior as learning opportunities. Help the child to develop ego strengths (the consciousness to be able to screen outside stimuli and control internal demands), which will result in better impulse control and thus increase self-esteem over time (Houck, Kendall, Miller, et al., 2011).

COMMUNITY-BASED NURSING CARE

Most children with ADD or ADHD are hospitalized only when needing care for another condition. Parents need support to understand the diagnosis and to learn how to manage the child. Emphasize the importance of a stable environment, at home as well as at school. At home the child may have difficulty staying on task. Parents need to consider age and developmental appropriateness of tasks, give clear and simple instructions, and provide frequent reminders to ensure completion. Routines in the evening can promote good sleep patterns.

The nurse can serve as a liaison to teachers and school personnel, or as the case manager for the child. An individualized education plan may be needed (see Chapter 12), with clear expected outcomes stated for the child's behaviors. Special classrooms or periods of instruction free from the distractions of the entire class may enable the child to improve school performance. Parents may have difficulty understanding the need for these approaches because the child often tests with above-average intelligence. Reinforce the importance of providing a structured environment free from unnecessary external stimuli. Be sure that parents understand behavioral approaches that will help the child, how to administer prescribed medications, and the importance of returning for healthcare visits to monitor for side effects. Medication should be locked safely away at home to keep it away from other children and prevent illegal use of this controlled substance. An individual school health plan may be needed for medication management.

Parents may have heard about ADHD in the media and often have many questions about its cause and management. Providing information about complementary and alternative treatments is a nursing role.

As the child grows older, explain the disorder and teach about techniques that will assist in dealing with problems. Assist in planning for a quiet environment during work. Encourage children with attention deficits to write down instructions from teachers and to use checklists to help them accomplish specific tasks.

Evaluation

Expected outcomes of nursing care for the child with ADD or ADHD include the following:

- Parents and child demonstrate understanding of the condition.
- Medications are administered and managed safely and as prescribed.
- The child demonstrates increased attentiveness and decreased hyperactivity, impulsivity, and sleep disturbance.
- The child demonstrates formation of a positive self-image.
- Educational performance is achieved to maximum potential.

Mood Disorders

Depression

Depression is psychologic distress that can range from mild to severe. Only in recent years has depression in children been recognized as a clinical condition. Many children referred to child guidance centers and mental healthcare providers because of behavioral difficulties or poor achievement actually suffer from depression. The incidence of major depression is estimated to be about 2% in childhood and up to 8% in adolescence; by age 18 years approximately 11% have had a depressive episode (Chung & Soares, 2012; National Institute of Mental Health [NIMH], n.d.a). A history of substance abuse and anxiety disorder increases risk, and cultural variations in rates exist.

ETIOLOGY AND PATHOPHYSIOLOGY

Theories have been proposed to explain the cause of depression in children and adolescents. Depression may be biologic in origin or a result of learned helplessness, cognitive distortion, social skills deficit, or family dysfunction. The physiologic theory focuses on monoamine neurotransmission. These amines include indolamine, serotonin, norepinephrine, and dopamine, and decreases are sometimes found in depression. Magnetic resonance imaging has identified brain changes in individuals who are depressed, suggesting a biologic basis (NIMH, n.d.a).

Developing Cultural Competence Depression Rates

Ethnic/racial differences in depression rates exist. The highest rates of depression are observed with Hispanic and Native American youth. Although there are scant data with Asian American youth, their rates of depression appear to be low. Data do not provide a clear picture of depression in African American youth as compared to White youth; in some studies, rates are higher and in others they are lower. In general, more female youth than male youth report depression (Lee & Liechty, 2014). It is probable that genetics, environment, and culture interact to influence the differences in prevalence of depression.

Parental depression and stress are predictive of childhood depression. Abuse and neglect, family conflict, parental death, and low socioeconomic status predispose children to depression. Other psychiatric diagnoses are common in children with depression; these include conditions such as ADHD, anxiety disorder, bipolar disease, or substance abuse (Emslie, Kennard, & Mayes, 2011).

CLINICAL MANIFESTATIONS

Characteristic findings of major depression in children and adolescents include declining school performance; withdrawal from social activities; sleep disturbance (either too much or too little); appetite disturbance (too much or too little); multiple somatic complaints, especially headaches and stomachaches; decreased energy; difficulty concentrating and making decisions; low self-esteem; and feelings of hopelessness. There is much variation among children in the symptoms displayed, and they often have some, but not all, of the major criteria. Symptoms vary according to children's developmental levels.

CLINICAL THERAPY

Youth should be screened for depression during well-child examinations or when indicated at other healthcare encounters (Agency for Healthcare Research and Quality [AHRQ], 2014). When depression or major depressive disorder is diagnosed, comprehensive assessment of the child should occur in order to rule out physical illness that can be linked to depressive symptoms, such as diabetes, cancer, and obesity. The child is tested for various mental health problems since comorbidities (combination with other disorders) are common. A history of bullying and substance abuse are examples of these comorbidities.

Initial assessment is performed by a child psychologist or child psychiatrist. A variety of scales and techniques are used; examples of useful tools are the Children's Depression Inventory (CDI), the Revised Children's Manifest Anxiety Scale, the Beck Depression Inventory (BDI-PC), the Guideline for Adolescent Preventative Services Questionnaire, the Patient Health Questionnaire for Adolescents (PHQ-A), the Reynolds Adolescent Depression Scale (RADS), and the Center for Epidemiological Studies Depression Scale for Children (CES-DC) (Stockings et al., 2014).

Treatment may include psychotherapy in combination with psychotropic medication. Often a combination of individual, family, and group therapy provides the greatest benefits for young children and adolescents. Involving parents, other family members, school personnel, and friends in the treatment plan is essential (Hughes & Asarnow, 2011). Group therapy is often effective for adolescents. Cognitive behavioral therapy (CBT) may be used with adolescents, and play therapy with younger children (see discussion of play therapy earlier in this chapter). CBT focuses on identification and restructuring of thoughts, feelings, and behaviors, leading to understanding of negative thoughts and increasing activities that provide pleasure (Mahoney, Kennard, & Mayes, 2011). Supportive interactions with healthcare providers and active problem solving are approaches that improve outcomes in adolescents. Healthcare providers should educate families about depression and counsel as needed. Confidentiality should be ensured. Refer to community resources as needed. Ensure a plan for safety of the adolescent.

Growth and Development

Symptoms of depression in children vary according to their developmental levels. Infants may fail to eat and grow. Toddlers can show regressive behaviors in toileting and other activities. Preschoolers have less symbolic and other play activities, may be irritable, and lack confidence. School-age children may show a decrease in academic performance, increased or decreased activity, somatic complaints, and loss of friends. Adolescents can have a wide array of symptoms such as anxiety, decreased social contact, poor school performance, lack of prior involvement in activities, poor self-care, difficulty with parents and teachers, or focus on violence (NIMH, n.d.a).

Antidepressant medications, most commonly the selective serotonin reuptake inhibitors (SSRIs), imipramine (Tofranil), desipramine (Norpramin), and amitriptyline (Elavil), may be prescribed. The only antidepressant approved to treat major depressive disorders in children and adolescents is fluoxetine HCl (Prozac), but clinicians sometimes use others when the youth does not respond to Prozac.

SAFETY ALERT!

The SSRIs act to block reuptake of serotonin in the synapse, so that serotonin levels (which influence mood) increase. Although the SSRIs are generally considered safer than some other types of antidepressants, their use in children has been limited, so side effects must be monitored. Generally, the child is started with a low dose, which is increased slowly to minimize the chance of side effects. Because of some reports of increased suicidal ideation and the lack of efficacy evidence, a psychiatric-mental health specialist must closely monitor children and adolescents taking SSRIs (AHRQ, 2014; NIMH, 2012a). A patient medication guide with the risks and precautions, as well as drug label information, must be provided for every client and family.

The major serious and life-threatening side effect of SSRIs is serotonin syndrome, a condition characterized by agitation, muscle twitching, gastric upset, chills, fever, confusion, and dizziness. It is more likely to develop when the child or adolescent is also taking St. John's wort, other antidepressants, alcohol, diet pills, or drugs such as ecstasy and LSD (Mayo Clinic, 2013b; Morrison & Schwartz, 2014). Be certain to ask questions in a nonjudgmental way about intake of any alternative therapies, other medications, or substance use to identify those most at risk.

Sudden cardiac death has occurred in several children on tricyclic antidepressants (TCAs). Because of this risk, serum levels should be monitored and electrocardiograms (ECGs) performed. Specific ECG changes along with a resting heart rate above 100, systolic blood pressure above 130 mmHg, and diastolic blood pressure above 85 mmHg necessitate immediate reporting to the prescriber. A narrow margin exists between the therapeutic and lethal doses in children (Weeke et al., 2012).

TABLE 28–4 Risk Factors for Child and Adolescent Depression

CHILD	FAMILY	SCHOOL AND SOCIAL SITUATIONS
• Frequent feelings of sadness, sleep problems, loss of interest in activities • Increase in risk taking and impulsivity • Previous suicide attempt • Alcohol or substance abuse • Diagnosed psychotic disorder • Chronic illness and frequent hospitalization	• Parental neglect, abuse, or loss • Dysfunctional family relationships • Family history of depression, suicide, substance abuse, alcoholism, other psychopathology	• Academic pressures and underachievement • Stressful social relationships • Declining participation in social events

Nursing Management

For the Child With Depression

Nursing Assessment and Diagnosis

Take a thorough history and physical examination, including observation of behavior, at the time of admission. Assess the child for common risk factors for depression (Table 28–4).

Several nursing diagnoses that might be appropriate for the child or adolescent hospitalized with depression are included in the accompanying *Nursing Care Plan*. Other diagnoses might include the following (NANDA-I © 2014):

- ***Self Neglect*** related to lack of energy and inability to perform daily hygiene
- ***Powerlessness*** related to sense of helplessness
- ***Self-Esteem, Chronic Low,*** related to negative self-evaluation

Planning and Implementation

Nursing care of the child or adolescent hospitalized for depression includes administering medications and other therapy and providing supportive care. Monitor vital signs of youth receiving antidepressant medications. Watch for common side effects of the agent(s) used. Carefully monitor for serious side effects of TCAs or SSRIs and be aware that lower doses are used at initiation, with doses increasing slowly to the desired level. Frequent face-to-face follow-up visits are needed. When dosages are altered, behavior and ideation changes must be closely monitored. Monitor cardiovascular status, including hypertension and tachycardia, observe motor movement, and record dietary intake. Help parents evaluate inpatient settings to be certain the care provided will best meet the needs of the child or adolescent. Refer to accompanying *Nursing Care Plan: The Child or Adolescent Hospitalized With Depression* for specific nursing interventions.

DISCHARGE PLANNING AND HOME CARE TEACHING

When the child has been hospitalized and is returning home, teach parents to recognize signs and symptoms of worsening depression. Also teach them dosages and side effects of any prescribed medications. Refer the family to appropriate healthcare providers and to support groups for family members dealing with depression.

COMMUNITY-BASED NURSING CARE

Most children with depression are cared for in the community. Maintain regular contact with the family through their healthcare visits to outpatient agencies and by making home visits. Monitor the child's affect, activity, and food intake. School teachers and counselors often are aware of the child's ability to perform in the school setting. Have the family schedule after-school care so young children are not left at home alone for extended periods.

Nursing Care Plan: The Child or Adolescent Hospitalized With Depression

1. Nursing Diagnosis: *Hopelessness* related to long-term stress (NANDA-I © 2014)

GOAL: The child or adolescent will discuss feelings of hopelessness.

INTERVENTION	RATIONALE
• Encourage open expression of feelings. Explore hopeless, sad, or lonely feelings. Point out the connection between feelings and behavior. Assess the child or adolescent to identify the precipitating event when feelings of sadness arose. Maintain an accepting and nonjudgmental attitude regarding any feelings expressed by the child.	• Expressing feelings may help relieve sadness, loneliness, despair, and hopelessness.
• Encourage the child or adolescent to take part in self-care and unit activities. Use routines to establish feelings of control.	• An active role in self-care and treatment helps the child or adolescent to feel more in control.
• Medicate as ordered and document results.	• Antidepressants modify mood to a more hopeful outlook.

EXPECTED OUTCOME: By discharge, child or adolescent will express an interest in the future.

(*continued*)

Nursing Care Plan: The Child or Adolescent Hospitalized With Depression (*continued*)

2. Nursing Diagnosis: *Coping, Ineffective,* related to inadequate social support or disturbance in pattern of appraisal of threat (NANDA-I © 2014)

GOAL: The child or adolescent will use effective coping skills.

INTERVENTION	RATIONALE
• Teach positive, effective coping strategies such as guided imagery and relaxation. Assist the child or adolescent to focus on strengths rather than weaknesses.	• Therapeutic techniques can help the child or adolescent to replace negative thoughts and images with more positive and effective beliefs and images. These interventions foster resilience.
• Assist the child or adolescent to identify friends, family members, and others who are positive and supportive.	• Helps the child or adolescent to become aware that people can be caring and supportive (thus validating self-esteem).

EXPECTED OUTCOME: Child or adolescent will verbalize and demonstrate ability to cope appropriately for his or her age.

3. Nursing Diagnosis: *Social Interaction, Impaired,* related to self-concept disturbance (NANDA-I © 2014)

GOAL: The child or adolescent will participate in and initiate activities and conversation.

INTERVENTION	RATIONALE
• Assist the child or adolescent to identify topics and activities of interest.	• The more the child or adolescent focuses on areas of interest, the less he or she will focus on internal anxiety and depression.
• Encourage interaction with peers and staff.	• Each positive interaction reinforces feelings of success. Each success reinforces the desire for future social interaction.
• Facilitate visits from family and friends.	• Reinforces positive and rewarding relationships.
• Provide guidance to family regarding interaction that promotes self-esteem.	• The family's existing interaction style is often negative.

EXPECTED OUTCOME: By discharge, child or adolescent will initiate conversation and activities with staff and peers.

4. Nursing Diagnosis: *Nutrition, Imbalanced: Less than Body Requirements,* related to loss of appetite secondary to depression (NANDA-I © 2014)

GOAL: The child's or adolescent's daily intake will be adequate to maintain optimal nutritional status.

INTERVENTION	RATIONALE
• Offer nutritious finger foods, sandwiches, and high-calorie liquid supplements frequently throughout the day.	• Convenient easy-to-eat foods encourage the child or adolescent to eat and maintain nutritional status.
• Offer easy-to-carry drinks that are high in vitamins, minerals, and calories.	• These are a convenient method for meeting hydration and electrolyte needs.
• Encourage daily vigorous physical activity of at least 30 min.	• Physical activity stimulates appetite.

EXPECTED OUTCOME: Child or adolescent's daily intake will be adequate to maintain optimal nutritional status by discharge.

Assist the family in finding support for financial and emotional needs related to managing the child's depression. Major expected outcomes for nursing care of the child with depression are found in the accompanying *Nursing Care Plan*.

Bipolar Disorder (Manic Depression)

Bipolar disorder is a mental illness in which extreme changes in affect and energy are manifested. Moods most often alter between mania (high energy and euphoria) and depression. Children often present with irritability or hyperactivity. About 1% of children and adults have bipolar illness, with a high rate of onset from 15 to 19 years, although onset as young as preschool age can occur. There is a high rate of attempted suicide in those with bipolar disease, as well as co-occurrence with other disorders such as ADHD, anxiety, and substance abuse, all of which complicate diagnosis (NIMH, n.d.b).

Families Want to Know

Selecting Residential and Inpatient Care for the Child With Mental Illness

Families need guidelines to help them evaluate inpatient facilities when a child with a mental disorder must be placed in an institution. You can refer them to the National Alliance for the Mentally Ill website. Provide questions for the families to ask:

- What is the staff-to-youth ratio?
- What are the guidelines for chemical and physical restraint?
- Are children isolated when behaviors are inappropriate?
- Are children constantly monitored visually when in restraint or when potentially dangerous to self or others?
- Does the child have a full physical and psychologic evaluation by a specialist within 24 hours of entry to the facility?
- What professionals review the plan of care and how often?
- Who can the family speak to for regular updates on the child?
- How often can the family visit?
- What services will be covered by insurance?
- What subjective feelings do the family members have as they visit the unit and facility?
- What services will be offered on an ongoing basis on discharge?

Bipolar disorder is classified into four types:

- *Bipolar I*—includes a severe manic episode that requires hospitalization or causes functional impairment in life
- *Bipolar II*—at least one episode of mild to moderate mania (hypomania) and one of depression
- *Cyclothymic disorder*—manifests as multiple mild manic and depressive episodes
- *Bipolar not otherwise specified*—rapid mood fluctuations, mania without depressive episodes, or chronic depression with hypomania episodes (NIMH, n.d.b).

When parents or close relatives are affected, the child is more likely to have the disorder. Thus, a genetic etiology is probable. It is believed that genetics and environment interact to create the condition in youth. Brain imaging shows abnormalities of the frontal and prefrontal cortex, the hippocampus, the basal ganglia, and the left amygdala, which is the center for experiencing fear (NIMH, n.d.b).

The manic phase of bipolar illness is characterized by hyperactivity and high energy, irritability, aggression, and sometimes hallucinations. In the depressive phase, the child is sad, has alterations in sleep and eating patterns, and is socially withdrawn, similar to any depressive illness. Mania may be the persistent symptom in children, or rapid cycles of mania and depression can occur throughout the day (Dineen, 2014; Kloos & Robb, 2011; Scrandis, 2014).

Diagnosis and treatment of bipolar disorder should be performed by mental health specialists. Use of alcohol or illegal drugs should be ruled out as a cause of symptoms, even in children. Since the manic phase is often manifested by hyperactivity, the child may incorrectly be treated with stimulants (see treatment of ADHD earlier in this chapter), and the disease can be worsened. Irritability, elation, labile moods, and sleep disturbance are commonly seen in children (Dineen, 2014; Kloos & Robb, 2011; Scrandis, 2014).

The treatment of bipolar disease involves a variety of drugs used to stabilize mood. Lithium, valproate, divalproex, carbamazepine, olanzapine, oxcarbazepine, lamotrigine, quetiapine, and risperidone are examples of drugs used; antidepressants may be prescribed (Blake, 2012; NIMH, 2012a). Only lithium has been approved by the FDA for use in those ages 12 to 18 years. However, clinicians prescribe other drugs with careful monitoring being performed. Early treatment is key to preventing chronic, serious mental illness. Individual and family education and therapy can be helpful.

Nurses are instrumental in identifying children with bipolar disorder, providing information to families, and monitoring the drugs and psychotherapy for the child. Nurses should observe for side effects to the specific drug regimen used and assist parents to find resources for health care since medications and other treatments may be costly. Parents and children need information about the disorder because it may recur several times during the child's life. Nurses can assist the child to find social events and groups that build a sense of self-esteem.

Anxiety and Related Disorders

A large group of anxiety disorders can affect youth as well as adults. Some of the more common types seen in children and adolescents are described in the following sections, with detailed nursing management described for posttraumatic stress disorder.

Generalized Anxiety Disorder

Anxiety is a subjective feeling of uncertainty and helplessness, usually accompanied by central nervous system (CNS) signs, including restlessness, trembling, perspiration, and rapid pulse. Anxiety is second only to substance abuse (see Chapter 17) in incidence for mental disorders and is a common mental disorder among children. From 4% to 20% of youth experience some type of anxiety disorder (Boydston, Hsiao, & Varley, 2012a; Sarvet & Brewer, 2011).

Anxiety disorders are strongly linked to familial and genetic factors. Diagnosis is performed by a mental health specialist, and treatment is usually cognitive behavioral therapy (CBT) and may involve medication. CBT can include child or family interventions that focus on relaxation, recognition of feelings, and self-talking (learned words or phrases said to oneself to aid in management of distress). Medications that have been reported to be successful in children include SSRIs and benzodiazepines (Boydston et al., 2012b).

Separation Anxiety Disorder

Separation anxiety disorder is characterized by an extreme state of uneasiness when in unfamiliar surroundings and often by refusal to visit friends' homes or attend school for at least 2 weeks. It is a common type of anxiety disorder manifested by children (Boydston et al., 2012a). Many children with separation anxiety disorder refuse to attend school at some point (see *School Phobia [Social Phobia]* section later in this chapter). This phobia

may be recurrent and become worse at certain times. The condition may be acute in onset (preceded by a traumatic event) or slow in developing over time.

Children with separation anxiety disorder tend to be perfectionistic, overly compliant, and eager to please. They appear to cling to the parent or caretaker. They may use physical complaints such as headaches, abdominal pain, nausea, and vomiting in an attempt to avoid being away from the parent. Depression frequently accompanies separation anxiety disorder. The resulting avoidant behaviors can interfere with personal growth and development, academic achievement, and social functioning.

Diagnosis is made by a mental health specialist. Treatment includes CBT with both child and parents. Parents learn about the disorder and how to structure the setting so that the child is expected to attend school. Consistency in expectations is needed since if the child is permitted to stay home some days or has missed school and other activities for longer periods, treatment is more difficult. The child learns what situations cause anxiety and how to manage the situations and feelings elicited. Both parents and child work out the expectations for behavior for the child with the mental health therapist; school personnel are included in the treatment plan. Medication can be used if CBT is not helpful.

Growth and Development

The separation anxiety commonly experienced by a 2-year-old differs from the psychiatric disorder in age appropriateness, duration, and severity. Separation anxiety disorder affects children of preschool age or older, lasts for at least 2 weeks, and is characterized by excessive anxiety. In contrast, the separation anxiety experienced by the 2-year-old involves a single episode of separation from a familiar caretaker and is a characteristic response in toddlers.

Panic Disorder

Panic disorder is the presence of recurrent, unexpected panic attacks. Panic attacks are periods of intense fear and discomfort in the absence of real danger. The lifetime risk of panic disorder is 2% (Boydston et al., 2012a). Predictive factors for panic attacks in adolescence include a history of separation anxiety or other anxiety disorder in life and a history of parental panic attacks.

Examples of the physical symptoms experienced are palpitations, sweating, chills, hot flashes, shaking, shortness of breath, choking, chest pain, nausea, and dizziness. The person describes feelings of danger or doom. Some people may have accompanying agoraphobia. **Agoraphobia** is anxiety about being in places or situations from which escape may be difficult or embarrassing, or in which help may not be available. The attacks may be continuous or episodic, but generally are chronic.

Diagnosis is made by a mental health specialist. Similar to anxiety, treatment may involve individual and family therapy, with use of medication in some cases. Nurses can help identify the disorder, refer for evaluation, and provide care in the community so that the child attends therapy sessions and takes medication as ordered.

Obsessive-Compulsive Disorder

People with obsessive-compulsive disorder (OCD) may be mildly or severely affected. Up to 2% of children are affected, and about 80% of adults with OCD had the condition in childhood (Boydston et al., 2012a). Affected children have recurrent obsessive thoughts, commonly about contamination, harm, sex, or moral concerns. These obsessions are handled through a series of compulsive behaviors that interfere with daily life. Examples of behaviors are excessive handwashing, counting objects, and hoarding substances. These practices may take 1 hour or more of time each day. Children with OCD differ from adults in several ways. They have more aggressive obsessions, such as fears of catastrophe, more commonly hoard objects, and are more likely to have religious obsessions. The presence of comorbidity with other mental health disorders is common.

The basal ganglia of the brain are affected and a genetic link is observed. A neurochemical cause may be related to abnormal serotonin metabolism. MRI changes in the globus pallidus and anterior cingulated gyrus of the brain have been noted. Poststreptococcal autoimmune disorder may be a cause in some cases (NIMH, 2012b).

Clinical Tip

Pediatric autoimmune neuropsychiatric disorders (PANDAS) are characterized by obsessive-compulsive and/or tic disorder, childhood onset, association with group A beta-hemolytic streptococcal infection, and neurologic abnormalities. It is believed that in certain children, the strep infection leads to a neural autoimmune response, resulting in the psychiatric disorder. Research continues to identify possible mechanisms, results, and treatments for this cause of OCD (NIMH, 2012b). *Pediatric acute-onset neuropsychiatric syndrome (PANS)* is the term used to refer to all cases of abrupt-onset OCD, not only those following streptococcal infection.

Diagnosis is made by a mental health specialist. Treatment may involve CBT, where the feared occurrence is presented and the person learns that no harm will occur. Involvement of the family in treatment is important so that members learn how to handle the child's ritualistic behaviors. Medications, such as clomipramine and the SSRIs, are effective in most children and adolescents. Nurses can identify cases and refer for mental health evaluation and provide teaching and support for families.

School Phobia (Social Phobia)

School phobia (also called *social phobia, school avoidance,* or *school refusal*) is a persistent, irrational, or excessive fear of negative evaluation or embarrassment in social situations and therefore of attending school. The child may fear being harmed or losing control. Social and school phobias occur in children as young as 5 years of age, often being present at 11 or 12 years, but can occur in children up to 16 years (Boydston et al., 2012a).

Children with social phobia may fear asking for directions, ordering food at a restaurant, and speaking in the classroom. They commonly report that teachers and peers "pick on" them. Somatic complaints are similar to those in children with separation anxiety disorder. Characteristically, symptoms are present only on school days and not on weekends or holidays. The social withdrawal that occurs in this disorder further impairs the child since social interactions are needed for normal developmental progression.

Diagnosis is made by a mental health specialist. Treatment includes the family and child, and establishes firm limits for behavioral expectations and consequences. CBT is used, including education of the youth about the condition, body awareness of symptoms, and methods of changing feelings. SSRI medications may sometimes be needed to lessen anxiety in social situations.

Conversion Reaction

Conversion reaction is a disorder in which a disturbance or loss of sensory, motor, or other physical functions suggests neurologic or other somatic disease. The disturbance or loss cannot be explained by any known pathophysiologic mechanism. Instead, psychologic factors are involved. About 3% of the population

experiences conversion reactions at some time. Adolescence and early adulthood are common times for the onset to occur, with onset being rare before 10 years or after 35 years of age (Kozlowska, Scher, & Williams, 2011).

Conversion reactions develop in response to a catastrophic event such as threat, loss, or harm. Clinical manifestations include altered sensations such as blindness or deafness; paralysis or ataxia, including inability to stand or walk and loss of ability to speak (aphonia); involuntary movements, such as pseudoepileptic convulsions; and constant complaints of pain with no physical basis (psychogenic pain). Children under 10 years old usually present with gait abnormalities or seizures. The onset of conversion symptoms is usually dramatic and sudden. Symptoms often appear to be neurologic, but on careful examination, obvious discrepancies are found. The person is usually calm about the symptoms even though they are serious. Often the child or family members appear indifferent or unconcerned over what healthcare providers consider an overwhelming physical disability.

Children suspected of having a conversion reaction require a complete physical and neurologic evaluation to rule out any possible physiologic basis for the symptoms. Individual and family therapy is usually necessary to identify the source of the psychologic conflict, pain, or need resulting in the conversion symptoms. Pharmacologic approaches may also be used.

Posttraumatic Stress Disorder

Acute stress disorder can occur after any life-threatening event and is manifested in the first month after exposure to the event. Symptoms include repeatedly reliving the traumatic experience, anxiety, and increased arousal. Similarly, people with *posttraumatic stress disorder (PTSD)* have experienced or witnessed a life-threatening event; however, the symptoms of distress continue for more than 1 month and cause impairment in functioning. Estimates of the incidence of PTSD are hard to obtain. It is assumed that about 40% of youth have an episode of trauma that could lead to PTSD, and there is a lifetime risk of 8.7% for the disorder. While 20% of children may experience PTSD after traumatic events, the prevalence rises to 90% when the trauma is severe (Boydston et al., 2012a).

Examples of events associated with posttraumatic stress include sexual or other child abuse, rape, car crash, fire, witnessing violence, and war experiences. Cassandra, described in the chapter-opening quote, was experiencing PTSD resulting from a frightening car crash as she was driven to school. She was too young to describe her feelings verbally to her mother or school personnel; however, she manifested the sleep abnormalities and other complaints common in the disorder.

The disorder involves both a traumatic event and the child's reaction to this event. It is believed that brain changes occur in trauma, leading to neurobiologic alterations that cause dysfunction of memory. Overreactivity of the amygdala, underreactivity of the prefrontal cortex, and increased dopamine in the medial prefrontal cortex are observed. Female gender, having other psychiatric disorders, a family history of psychiatric illness, and severe or lengthy trauma are all risk factors.

Common reactions in persons with PTSD are intrusive symptoms such as negative thoughts and feelings, avoidance of reminders of the event, and arousal or hyperreactivity to events (American Psychiatric Association, 2013). The child with PTSD has feelings of fear, terror, and helplessness, and may relive the event frequently in thought and nightmares. The child may become emotionally numb in a subconscious attempt to protect the self, but may have a persistently increased state of arousal. The child exhibits a state of hypervigilance and an exaggerated startle response, such as to touch or loud noises. The child with PTSD is often irritable, and has sleep problems and inattentiveness. The child feels detached from others and alone. Immediately after the event, the child may appear to have adapted and functions normally. However, after several weeks or even months, the symptoms of the disorder begin to appear.

The diagnosis is made by a mental health specialist; a variety of instruments assist in screening for the disorder. Counseling by a mental health specialist is the main therapy for PTSD. Cassandra saw a clinical psychologist who used play therapy to help her communicate her fears related to a car crash (Figure 28–6). CBT is the treatment of choice, with both the child and family members

Clinical Reasoning Posttraumatic Stress Disorder

Cassandra is a 9-year-old girl who has recently become fearful about attending school and has awakened crying at night. She is in the third grade at a school she has attended for 2 years. A few weeks ago, she was in a car crash as her mother drove her to school. She received only minor injuries and returned to school the next day. However, her mother believes that Cassandra's behavior has been worsening since the car crash. She spoke with the school nurse, who is aware of no trauma at school, but did learn from the teacher that Cassandra has not been paying attention in class recently. Cassandra cannot explain why she does not want to go to school, only that her stomach aches or some other part of her body hurts.

Cassandra visited her pediatrician, who ruled out any physical cause for her complaints, and referred her to a child psychologist. The psychologist has scheduled several sessions with Cassandra to help her learn to verbalize her fears and learn strategies to deal with them. She uses dolls in an attempt to help Cassandra act out her fears and gain some understanding. The psychologist communicates Cassandra's progress to you, the school nurse.

- How can you ensure Cassandra's attendance at school?
- What does the teacher need to know to support Cassandra in the classroom?
- What is your role as liaison between the psychologist, family, and school personnel?
- Parents often feel guilty when a child experiences a mental health disorder. What type of information and support do Cassandra's parents need?

Figure 28–6 **The psychologist uses play therapy to help Cassandra reenact her car crash. This helps her gain some control over the event so that it is not so frightening.**

Figure 28–7 **This nurse conducts a group therapy session for children who have experienced traumatic events and have resulting anxiety disorders. He is clearly engaged, has a positive rapport, and fosters exchanges among the children. Playing games and drawing are frequent techniques used in the group.**

included. Young children show significant improvement in symptoms after a course of CBT (Center for Injury Research and Prevention, 2011). A variety of antidepressants and SSRIs are used for pharmacologic treatment.

Nursing Management

Nurses often help identify PTSD victims so that care can be obtained. Ask about traumatic events in the past and how the child reacted. Inquire about recent changes in the child's behavior. Include school attendance, complaints of physical illness, sleep patterns, and rituals in behavior. A family history of mental disorders may be useful. Youth who run away from home and present at homeless shelters are often suffering from PTSD. Assessment for the condition should be part of the initial history.

Nursing care for anxiety disorders focuses on behavioral and cognitive therapies to enhance coping skills. Mental health nurses may conduct group therapy sessions (Figure 28–7). Group sessions for children often provide a forum for discussion of fears, an opportunity to enhance skills of working together, and an opportunity to learn coping skills. Being a member of a group with other children experiencing anxiety or trauma can remove the stigma and allow the child the freedom to explore the behavior and its causes. Several of the techniques described in the chapter, such as drawing pictures and discussing them or telling stories, are used by mental health nurses in child therapy groups (Boydston et al., 2012b).

Children need to learn relaxation techniques and nurses may teach such techniques or recommend that the child consider participation in yoga or guided imagery classes. Inquire about alternative therapies that the child and family are using or have an interest in beginning, and refer as needed. Parents or other significant people should be included in the treatment program. Nurses often teach them basic information about the child's diagnosis and therapy. They should be in at least some therapy sessions with the child. Provide the family with resources that will assist with relief from worry about the child, guilt about causing an accident that triggered the child's symptoms, or other feelings related to the diagnosis.

Insurance companies may provide limited payment for mental health services. Help the family to see the importance of recommended therapy and assist them to find resources for care if needed. School personnel may need to know about the child's treatment. Partner with the families to provide needed information. Some schools have counselors that can be instrumental in carrying out treatment plans at school and acting as a resource in that setting. School personnel may be asked to provide feedback about the child's attendance, performance, and social skills as a measure of the success of therapy, and the community or school nurse can relay this information.

Families Want to Know

Talking With Children About Traumatic Events

Whether a child or adolescent experiences trauma from a car crash, abuse, or environmental event, parents can help to decrease the effects of the stress and prevent the appearance of PTSD. Some suggestions for parents include:

- Be sure children feel free to ask parents, teachers, or others about the events and their feelings.
- Assure children that their feelings are common and the stress may return now and then over time.
- Be honest and open in responses, without overloading children with more details than they need.
- Be prepared to repeat answers and discuss the same topics many times.
- Get help from counselors who can suggest how to talk with the child.
- Use communication methods appropriate at various ages, such as reading books, doing art projects, or drawing.
- Show children that they are loved by spending time and planning activities with them.
- Limit the television and other media time where the child is exposed to violence and traumatic events.
- Restore a sense of normal routines into the child's life.
- Be alert for increasing signs of distress and seek care from a professional if they occur.

Nurses often administer medications to children being treated for PTSD and other mental health concerns. Be alert for side effects and ensure the family knows how to safely administer the drugs. These drugs should be kept locked securely. Have the child return for follow-up as needed since some medications may take several weeks to achieve effects, and close monitoring is essential. The child should wear a medication alert identification for drugs being taken.

Other Disorders

Suicide

Suicide is the third leading cause of death in adolescents between 15 and 19 years of age. About 4400 youth commit suicide annually, and an additional 149,000 receive care after attempted suicide. In any 1 year, over 15% of youth admit to contemplating suicide (CDC, 2012b). The prevalence of suicide is about 7.32 per 100,000, with 86% of the deaths among male adolescents. Firearms, suffocation, and poisoning are the most common means of suicide (CDC, 2012b).

Developing Cultural Competence **Suicide, Gender, and Ethnicity**

Some ethnic groups have a high rate of suicide. For example, Native Americans and Alaskan Natives have a rate of suicide of 31/100,000, while for all other youth the rate is 12.2/100,000. The historic pain experienced by this ethnic group and lack of opportunities for many youth may be some of the reasons for a high suicide rate. Hispanic female adolescents have a high rate of suicide attempts. Males have a high rate of suicide at 4 times that of females; males more often use firearms, while females more commonly use poisoning (CDC, 2012b).

Healthy People 2020 goals focus on eliminating such health disparities by finding the causes, decreasing rates of suicide, educating about risk factors, and establishing prevention programs (U.S. Department of Health and Human Services [USDHHS], 2015).

Healthy People 2020

(MHMD-2) Reduce suicide attempts by adolescents from the present 1.9/100 to 1.7/100 (a 10% improvement)

It is not unusual for healthcare providers and parents to label suicide attempts by children and adolescents "accidents." Up to one half of childhood suicides may be recorded as accidents; suicide data for children under age 10 years are not maintained. Adults may have difficulty believing that young children, in particular, would have any reason to want to end their lives. Because of this, many children brought to the emergency department with indications of a suicide attempt are often classified as unintentional injury victims and released without arrangements for appropriate follow-up care. Accurate identification and treatment are needed for youth at risk of suicide.

Many risk factors for suicide exist in children and adolescents, while some protective factors are influential as well (Table 28–5). The most common precursor to adolescent suicide is depression (see earlier discussion in this chapter). Common signs or symptoms of an underlying depression that could lead to suicide include boredom, restlessness, problems with concentration, irritability, lethargy, intentional misbehavior, preoccupation with one's own body or health, and excessive dependence on or isolation from others (especially adults or caregivers).

TABLE 28–5 Risk and Protective Factors for Suicide in Children and Adolescents

RISK FACTORS	PROTECTIVE FACTORS
History of previous attempted suicide	Emotional well-being
Friend committed or attempted suicide	Satisfactory school performance
School problems or changes in grades	Participation in sports or other group events
Pregnancy	Weight satisfaction
Drug use or abuse	Parent/family connectedness
Problems with a romantic relationship	Frequent discussions of important issues with family
Minority sexual practice	School connectedness
Loneliness, withdrawal	Safe school
Feelings of anxiety	Safe neighborhood
History of chronic family problems	Caring adult presence at school or elsewhere
Chronic illness	Availability of school counseling
Physical, emotional, or sexual abuse	School policies to limit and cope with fighting, bullying
History of suicide in a family member	
History of depression	
Chronic low self-esteem	
Change in behavior	
Change in weight	
Giving away special possessions	
Access to firearms and ammunition	

The child or adolescent at high risk for suicide may be admitted to a mental health unit for care or cared for in a community mental health facility. Treatment may include individual, group, or family therapy. Negotiating a "no suicide" contract is one method that may be used with a suicidal youth. In the contract, the child agrees not to attempt suicide during a specified time period. When a suicide attempt is made, the child or adolescent may be hospitalized for 24 hours, kept in a short-term monitoring unit, or sent home under close observation to ensure adequate assessment and monitoring. It is important to provide crisis intervention at the time of the suicide attempt to minimize the opportunity for repeat attempts and to begin a therapeutic treatment plan.

Nursing Management

The major nursing role is in prevention of suicide. All children and adolescents in health promotion visits and emergency departments should be evaluated for risk. Health promotion visits are an opportunity to be alert for children with depression (see previous discussion in this chapter), substance abuse, recent stresses, and changes in behavior. Inquire about sleep patterns, feelings of sadness, and use of alcohol and other substances. Gather a family history of mental health disorders, suicide attempts, and stresses.

Ask about how often the youth talks with or has meals with the family. Be aware of the risk of self-inflicted strangulation.

SAFETY ALERT!

A tragic cause of unintentional suicide in children is the choking "game." About 25 children with a mean age of 13 years die each year in the United States from this practice. When the blood supply to the brain is interrupted and then rushes back, some people report a feeling of euphoria or a "high." Children and adolescents may seek the experience for the feelings it creates and may even become addicted to it. Unfortunately, some children become unintentionally strangled and die from the experience. Methods that children use to cut off oxygen include using their hands to apply pressure to the carotids in the neck, or tying belts, cords, towels, and other items to the neck and then around doorknobs or other solid objects. Some children perform these rituals with others who then rescue them so that they begin breathing; many of the injuries occur when children are alone and there is no one to perform a rescue. Teachers, parents, and other adults typically have not heard of or are unaware that children are performing these rituals. Adults can watch for signs such as conjunctival hemorrhage, headaches, bruising in the neck area, periods of disorientation, hoarseness, and finding items tied to doors and other solid objects. Parents can also be alert if the history of a family computer has shown the child's entry to a website that describes the practice. Nurses in schools and other settings should educate children about the dangers of strangulation and should provide materials for parents to inform them of the risk (CDC, 2008, 2010; Mechling, Ahern, & McGuinness, 2013).

Recall that all youth who receive medications for treatment of depression should be carefully monitored, especially in the first several weeks in order to identify those who may develop suicide ideation and risk. Although antidepressants have demonstrated efficacy for treating depression in youth, there is an increased risk of suicidal ideation or behaviors in children and adolescents treated with these drugs.

Most suicides are committed with firearms that are usually obtained from the home. Determine at each healthcare visit if the family has firearms. Teach adults to keep the guns unloaded, with ammunition and firearms locked in separate locations. Be sure that children and adolescents do not have access to the keys for the locked firearms. Never underestimate the resourcefulness or abilities of a suicidal child or adolescent, regardless of age, IQ, or physical abilities.

Education in all school settings is appropriate to teach children about resources that can help them if they need it and to identify peers at risk. Mental health services of all types should be available and embedded in schools since that is the setting where youth spend much of their time (USDHHS, 2015). Be alert for children and adolescents at risk for suicide in any setting. Assess children and adolescents in schools, outpatient settings, and emergency departments for the possibility of suicidal behavior. Report threats of suicide and depressive behavior. When a child or adolescent persists in threatening suicide after establishment of a "no suicide" contract, hospitalization is necessary to ensure safety. Recognize that when a child or adolescent has committed suicide, friends of the victim may be at increased risk. Teach students to report to teachers, nurses, or counselors about friends who have threatened suicide or seem depressed or display behaviors different from usual. Nurses often plan with mental health specialists to implement suicide prevention programs in schools and communities. Provide supportive services to family and friends whenever suicide occurs. Consult websites and refer parents as appropriate. The Suicide Prevention Resource Center has helpful regional offices to facilitate networks at national, state, territorial, community, and tribal levels (Maheshwari & Joshi, 2012).

Professionalism in Practice **Suicide Prevention**

The U.S. Surgeon General and the National Action Alliance for Suicide Prevention presented the 2012 National Strategy for Suicide Preventions: Goals and Objectives for Action. Major strategies were focused around empowering individuals, families, and communities by increased knowledge; providing comprehensive clinical and community preventive services; providing treatment and support for individuals and families when needed; and conducting surveillance, research, and evaluation (USDHHS, 2012). Nurses have a role in each of these strategies by identifying risk and providing connections to services, integrating suicide prevention in all healthcare settings, and collecting evaluative data from their communities.

Nursing care during hospitalization for suicide centers on taking appropriate precautions to ensure the child's safety. Be alert for children and adolescents in the emergency department who may have attempted suicide (Schmid, Truong, & Damian, 2011). Monitor both the child and the hospital environment for any object that could be used for self-harm. Remove all potentially harmful objects, such as shoestrings, belts, pantyhose, and hair ribbons. Keep all personal care items (including toothbrush and shampoo) locked at the nursing station and monitor them constantly when used by the child.

Children or adolescents considered at high risk for suicidal behaviors are attended to by a nursing staff member at all times, including while using the bathroom and sleeping. It may be necessary for the child to dress in a plain hospital gown, be kept in a visually monitored seclusion room, or (if seriously impaired and self-abusive) be medicated for restraint for a period of time. Restraints are used only when ordered by the youth's physician and collaborative care team. Physical restraint is only a short-term approach to provide immediate safety if necessary. Chemical (medication) restraint may be needed to prevent self-injury by the suicidal person. See *Families Want to Know: Selecting Residential and Inpatient Care for the Child With Mental Illness* earlier in this chapter for information to help families consider when choosing care for their suicidal child.

Hospitalization continues as long as the child's behavior is self-destructive. Children are referred for intensive individual and family therapy. Encourage parents to keep follow-up clinic appointments, to watch for self-destructive behaviors, and to administer any prescribed medications according to the treatment schedule. Arrange home visits and other community resources for families. Desired outcomes include an increase in coping skills for the child, no further suicide attempts, and an improved sense of well-being.

Tic Disorders and Tourette Syndrome

Tics are sudden, rapid, recurrent, nonrhythmic, and brief motor movements or vocalizations. They may involve movement of the head or upper body, blinking of eyes, or a variety of verbal noises. They may be worse during periods of stress or tiredness. Many children have mild motor tics at some time that gradually

disappear with no intervention. When the tics are severe or last more than 1 year, they are considered chronic and may require attention from a mental healthcare provider.

Severe motor tics accompanied by verbal utterances are known as *Tourette syndrome*. The syndrome is often accompanied by other diagnoses such as attention deficit and learning disabilities. Children with Tourette syndrome may exhibit coprolalia, the involuntary utterance of obscenities, profanities, and racial slurs, or copropraxia, the involuntary use of obscene gestures. Tic disorders are characterized by disruptions in the levels of dopamine, serotonin, and other neurotransmitter and neuropeptide levels (National Institute of Neurological Disorders and Stroke, 2014).

Nursing care involves supporting parents and encouraging normal developmental progression for the child. Nurses should carefully monitor symptoms after medication is begun, minimize stress, and teach relaxation techniques.

Schizophrenia

Schizophrenia is a psychotic disorder that is relatively rare in young children and adolescents, occurring in 1 in 10,000 children. The condition can manifest in childhood but is more common in adolescence (Lachman, 2014; Mayo Clinic, 2014).

The cause of schizophrenia is unknown, but genetic predisposition or neurointegration deficits are suspected causes (Mayo Clinic, 2014). The brain is altered in the disease, with progressively enlarged ventricles and nervous system arousal. Impaired glucose metabolism is often present. Onset is usually slow with increasing intensity. Most often the child demonstrates restlessness, poor appetite, and social withdrawal over several weeks to months. Behavioral problems, slowed development, and minor neurologic symptoms may occur.

The clinical manifestations of schizophrenia are the same in children as in adults. Characteristic behaviors include social withdrawal, impaired social relationships, flat **affect** (outward appearance of feeling or emotion), regression, loose associations (thought characterized by speech in which ideas shift from one subject to another that is unrelated), poor judgment and problem solving, anxiety, delusions, and hallucinations. Motor abnormalities may include rocking and arm flapping.

During adolescence, acute schizophrenia can occur suddenly while the teenager is making plans to leave home and family to attend college, marry, or work in another area. Onset of symptoms may be triggered by an important loss (death of a significant other, parent, child, or friend).

Prompt diagnosis can lead to early treatment and more positive outcomes. Clinical therapy for childhood schizophrenia is multifaceted, including individual psychotherapy, family therapy, and various psychotropic medications (antipsychotics such as haloperidol [Haldol], clozapine, olanzapine, risperidone, antianxiety agents such as lorazepam [Ativan], and antidepressants such as imipramine [Tofranil]) (Lachman, 2014; Mayo Clinic, 2014). Drugs are only moderately effective at controlling hallucinations and delusions. Responses vary considerably, and children may have different responses than adults. Side effects determine what drugs are used and for how long. Antipsychotic medication is continued for at least 4 to 6 weeks before effectiveness can be determined. Medications often must be continued for several months or years after recovery from an acute schizophrenic episode, although medication-free trials may be tried in children who have not shown symptoms for 6 to 12 months.

Episodes of acute schizophrenia may require inpatient hospitalization on a psychiatric unit for thorough diagnosis and beginning management. Treatment may include an intensive school-based program in a structured, supervised setting with specially trained professionals. The goal of initial treatment is to reduce or control schizophrenic episodes and provide a safe, structured environment for the child or adolescent, enabling the child to live each day at an optimal level of functioning. Outpatient care is provided in the community following initial diagnosis and establishment of a treatment regimen.

Most children with acute schizophrenia require long-term treatment, including intermittent periods of hospitalization. Children or adolescents whose symptoms are difficult to control and who present a safety risk to themselves or others may require long-term residential treatment. Earlier age at diagnosis and delay in treatment lead to poorer prognosis.

Nursing Management

The nurse may encounter the child or adolescent with schizophrenia during hospitalization for an acute episode, for treatment of another problem, or while working with the individual in the community. Nursing care centers on providing for physical safety and psychologic care, and normal growth and development for the child.

Family education and involvement in the treatment plan are essential. Teach the family to monitor the child's symptoms and progression. Educating the child and parents about the risk of recurrence and methods to alleviate side effects of prescribed medications may increase compliance with the treatment plan. Assess the child for common medication side effects. For example, when excess weight is a potential side effect, frequent growth measurements are made. Neurologic assessment and laboratory studies may be needed with some medications. Help the family establish educational plans and integration within the school system. Communicate with school personnel to ensure understanding of the child's condition and ongoing management of the individualized education plan.

Cognitive Alterations

A wide array of cognitive conditions occur in childhood. Some are mild and not diagnosed until a child has difficulty in school, whereas others may be associated with physical signs that are visible at birth. Two common conditions, learning disabilities and intellectual disabilities (mental retardation), are discussed in this section.

Learning Disabilities

Learning disabilities are a common problem of young children, affecting about 5% to 10% of school children (Boyle et al., 2011; CDC, 2013). They involve neurologic conditions in which the brain cannot receive or process information in the normal manner. Often the impairment is only in one or two types of learning, making diagnosis difficult. Common types of learning disorders are listed in Table 28–6.

Children may have difficulty processing visual information, which may be manifested in reading, writing, and mathematics performance. Others may have difficulty with oral information, leading to problems in language development and reading.

TABLE 28–6 Examples of Learning Disabilities

DISORDER	CLINICAL MANIFESTATIONS
Dyslexia	Difficulty with writing, reading, spelling
Dyscalculia	Mathematics and computation problems
Dysgraphia	Difficulty with writing, spelling, and composition
Dyspraxia	Problems with manual dexterity and coordination

The causes of learning disorders are complex. Sometimes they are related to low birth weight or problems during the perinatal period. There may be a genetic component since their occurrence is more common when other family members are affected.

Learning disabilities should be diagnosed by a learning specialist such as a psychologist with special training. A series of cognitive and developmental tests are commonly used; magnetic resonance imaging (MRI) is sometimes used. Treatments involve learning how to compensate for the difficulties by using capabilities that are intact. Some children need to have all material written for them, and others need to have verbal presentations. Specific learning goals are established with the assistance of learning specialists. Children with learning disabilities should have individualized education plans (IEPs) established with realistic goals for school performance. (See Chapter 12 for further information about IEPs.)

Nurses play a major role in identifying children with learning disabilities. The nurse may be in contact with families during health promotion visits or in other settings when parents relay concern about the child's performance or difficulty in some aspect of school. Nurses should assess the child for the following developmental milestones, which can indicate learning disability (National Joint Committee on Learning Disabilities, 2015):

- Tasks such as tying shoes, buttoning, or hopping
- Expressive and receptive speech
- Naming objects or reading
- Fine and gross motor milestones
- Following simple instructions

When a child may have a learning disability, the nurse should refer the family to the school or other testing resource. The nurse should partner with the family to plan for the child's learning needs, help the family work closely with the child, suggest providing a setting at home to maximize potential for learning, and offer suggestions for building healthy self-esteem in the child. The nurse should assist the family to work with the school to establish annual goals for the child. Most children with learning disabilities can learn to perform well in their areas of strength and compensate for areas of difficulty. Early intervention is key to success and building a positive self-image regarding abilities.

Intellectual Disability (Formerly Called Mental Retardation)

Intellectual disability is now the preferred term for what was previously called *mental retardation*. **Intellectual disability** is defined as significant limitation in intellectual functioning and adaptive behavior. It is manifested as differences in conceptual, social, and practical adaptive skills, beginning before the age of 18 years (American Association on Intellectual and Developmental Disabilities, 2013). Later events that lead to limitations in function are commonly referred to as *brain injury*. Intellectual functioning is generally characterized by an intelligence quotient (IQ) below 70 to 75, accompanied by significant impairments in **adaptive functioning** (the ability to meet the standards expected for a cultural group). The child with intellectual disability has adaptive deficits in at least two areas such as communication, self-care, home living, social/interpersonal skills, use of community resources, self-direction, functional academic skills, work, leisure, health, or safety. A low IQ score by itself does not necessarily correlate with an impaired ability to carry out adaptive skills. The child should be evaluated within the contexts of the individual cultural and community environment. The IQ score and the level of adaptive skills together determine the degree of severity of intellectual disability.

Intellectual disability is one type of **developmental disability**, any of a variety of chronic conditions that are characterized by mental or physical impairments. Other examples include pervasive developmental disorder, cerebral palsy, and sensory loss. A developmental disability begins by age 21 years and lasts throughout life.

ETIOLOGY AND PATHOPHYSIOLOGY

Intellectual disability occurs in 12 per 1000 children, a decrease from 15.5 per 1000 a decade ago (CDC, n.d.). Its causes can be grouped into three general categories: prenatal errors in the development of the central nervous system, prenatal or postnatal changes in the person's biologic environment, and external forces leading to central nervous system damage. In each instance, the precipitating factor changes the form, function, and adaptation of the central nervous system. Table 28–7 provides examples of common conditions associated with intellectual disability.

SAFETY ALERT!

Zika virus is transferred to humans by the bite of the *Aedes* mosquito, which is most common in tropical, moist climates. An infected sexual partner can also transfer the virus. The symptoms found in most people with Zika virus disease are common to many viral illnesses: fever, rash, fatigue, conjunctivitis, and muscle aches. Since 2015, an increase in disabilities to women who contracted Zika virus in pregnancy was noted in Brazil. Further studies indicate that fetuses exposed to Zika virus have a higher risk than normal of being born with microcephaly (small head and brain), hearing problems, vision disabilities, and growth dysplasia. Much research is being carried out to learn about the disease, its transmission, and its effects on the fetus. No immunization is available against the virus, so protection from mosquito bites, ensuring protected sex with partners who have been exposed or infected, or delaying pregnancy if exposed to geographic areas where the virus is common are the only methods of known prevention (CDC, 2015).

Three conditions from prenatal life that are associated with intellectual disability are Down syndrome, fragile X syndrome, and fetal alcohol syndrome. In the United States, about 1 in 700 infants, or 5500 infants each year, are born with Down syndrome (CDC, 2014c). The syndrome is caused by an extra chromosome; the child has 47 rather than 46 chromosomes. (See discussion of genetic transmission in Chapter 3.) The most common chromosome affected is 21 so that the child often has "trisomy 21," or three instead of two copies of number 21 chromosome. In addition to intellectual disability and physical signs, the child with Down syndrome is at higher risk of developing other conditions such as cardiac defects, hearing loss, gastrointestinal problems, orthodontic conditions, thyroid disease, dermatologic conditions, and leukemia (CDC, 2014c).

TABLE 28–7 Common Conditions Associated With Intellectual Disability

PRENATAL CONDITIONS	BIOLOGIC ENVIRONMENT	EXTERNAL FORCES
Down syndrome Fragile X syndrome Fetal alcohol syndrome Maternal infection (e.g., rubella, cytomegalovirus)	Inborn errors of metabolism (e.g., phenylketonuria, hypothyroidism)	Traumatic brain injury (e.g., accident) Poison ingestion (acute or chronic) Hypoxia/anoxic insult Infection (e.g., meningitis) Environmental deprivation

Fragile X syndrome is caused by a single recessive gene abnormality on the X chromosome. A permutation to the X chromosome may occur in males or females. When a father or mother passes the faulty X chromosome to a daughter, it may remain as a permutation or may change into a true mutation. The daughter has two X chromosomes and therefore does not manifest this recessive disorder. However, she can pass the mutated X chromosome to her son who becomes affected with fragile X. The mutation of fragile X is on gene *FMRP-1*, which instructs cells to make a protein necessary for normal brain development. The faulty gene creates a deficiency in the FMRI protein that leads to brain changes. The condition is often associated with other conditions such as sudden death heart disease (SDHD), anxiety, and autism (CDC, 2014d).

Fetal alcohol spectrum disorder (FASD) describes the wide range of effects of ethyl alcohol on the developing fetus. The condition ranges from alcohol-related birth defects (ARBDs), such as disorders of the heart, kidneys, bones, or hearing; to alcohol-related neurodevelopment disorder (ARND), such as intellectual disability; to fetal alcohol syndrome, which is the most severe end of the spectrum, leading to a combination of mental health and intellectual and physical problems (CDC, 2014e). Alcohol ingestion by the pregnant woman can influence development of many body organs, and effects can range from mild to severe. Despite many years of public health education, alcohol use remains a leading cause of intellectual disability. From 0.3 to 1.5 per 1000 births are affected by fetal alcohol syndrome (CDC, 2014e).

For a discussion of phenylketonuria and hypothyroidism, two common biochemical causes of intellectual disability, see Chapter 30. Other causes involve traumatic brain injury and infections of the central nervous system (see Chapter 27). Intellectual disability is more common in children born prematurely.

CLINICAL MANIFESTATIONS

Mild intellectual disability was originally described as an IQ between 50 and 70, moderate disability with IQ of 35 to 50, severe disability with IQ 20 to 35, and profound disability below 20. Although an IQ below 70 is generally considered indicative of intellectual disability, the functional assessment of the child is now considered a more accurate identification of children's performance and needs. Children who have intellectual disabilities manifest delays in all areas of development, including motor movement, language, and adaptive behavior. They usually achieve developmental milestones more slowly than the average child. These developmental delays may be the first indication to parents, teachers, and healthcare providers of the child's condition.

Intellectual disability is sometimes accompanied by sensory impairment, speech problems, motor and orthopedic disabilities, and seizure disorders. Of children with the disability, 10% to 30% manifest one of these other disorders. Table 28–8 lists several physical characteristics associated with Down syndrome, fragile X syndrome, and fetal alcohol syndrome.

Developing Cultural Competence Fetal Alcohol Syndrome

Fetal alcohol syndrome is more common in groups with higher intake of alcohol. Because some Native American tribes have a high rate of alcoholism, the federal government and some tribes have joined together to lower that risk among this ethnic group. Some reservations, such as the Yakama Nation in Washington State, do not sell alcoholic beverages and have put educational programs in place.

TABLE 28–8 Characteristics Associated With Three Common Types of Intellectual Disability

SYNDROME	CHARACTERISTICS
Down syndrome (see Figures 5–8 and 5–33)	Small head (microcephaly) Flattened forehead Wide, short neck Epicanthal eye folds White spots on eye iris (Brushfield spots) Congenital cataracts Flat nose Small, low-set ears Protruding tongue Short broad hands Simian line on palm Wide space between first and second toes Hearing loss Increased incidence of diabetes, congenital heart defect, and leukemia Hypotonia
Fragile X syndrome	Long face Prominent jaw Large ears Frequent otitis media Large testicles Epicanthal eye folds Strabismus High arched palate Scoliosis
Fetal alcohol syndrome (see Figure 4–4)	Flat midface Low nasal bridge Long philtrum with narrow upper lip Short upturned nose Poor coordination Failure to thrive Skeletal and joint abnormalities Hearing loss

CLINICAL THERAPY

Intellectual disability is diagnosed and initial treatment is planned in a multistep process, and by involving a collaborative care team. Team members may include a developmental specialist, physician, geneticist, nurse, teacher, language therapist, occupational therapist, and physical rehabilitation specialist. See Table 28–9 for a description of the *DSM-5* diagnostic criteria for intellectual disability. Diagnosis begins with a comprehensive history and evaluation of the child's physical characteristics, developmental level, and intellectual and adaptive functioning. Laboratory tests such as chromosome analysis, blood enzyme levels, lead levels, or cranial imaging provide valuable information in some circumstances. A three-generation family history is performed.

Developmental screening (see Chapter 6) can help identify children at risk. Tests of intellectual and adaptive functioning are performed when disability is suspected. A neurologic examination may indicate asymmetry of movement or strength, irritability or lethargy, or abnormal pitch to an infant's cry. Because intellectual disability may be accompanied by physical abnormalities, it is important to observe the child for facial symmetry, distance between the eyes, level of the ears, hair growth, and palmar creases. These abnormalities may be clues to other health problems.

TABLE 28–9 *DSM-5* Diagnostic Criteria for Intellectual Disability

Intellectual disability (intellectual developmental disorder) is a disorder with onset during the developmental period that includes both intellectual and adaptive functioning deficits in conceptual, social, and practical domains. The following three criteria must be met:

1. Deficits in intellectual functions, such as reasoning, problem solving, planning, abstract thinking, judgment, academic learning, and learning from experience, confirmed by both clinical assessment and individualized, standardized intelligence testing.
2. Deficits in adaptive functioning that result in failure to meet developmental and sociocultural standards for personal independence and social responsibility. Without ongoing support, the adaptive deficits limit functioning in one or more activities of daily life, such as communication, social participation, and independent living, across multiple environments, such as home, school, work, and community.
3. Onset of intellectual and adaptive deficits during the developmental period.

Note: The diagnostic term *intellectual disability* is the equivalent term for the diagnosis of *intellectual developmental disorders*. Moreover, a federal statute in the United States (Public Law 111-256, Rosa's Law) replaces the term *mental retardation* with *intellectual disability*, and research journals use the term *intellectual disability*. Thus, *intellectual disability* is the term in common use by medical, educational, and other professions and by the lay public and advocacy groups.

Specify current severity as:

- Mild
- Moderate
- Severe
- Profound

Source: Used with permission from American Psychiatric Association. (2013). *Diagnostic and statistical manual of mental disorders* (5th ed.). Washington, DC: Author. Copyright © 2013 American Psychiatric Association.

Based on the results of the evaluation, a multidisciplinary team plans the support needed to maximize the child's potential for development. Management focuses on early intervention to improve the degree of adaptive functioning. Associated physical, emotional, and behavioral problems are treated simultaneously. Depending on the child's condition, special education programs and physical or occupational therapy may be necessary (Figure 28–8). The Education for All Handicapped Children Act (PL 94-142) provides free appropriate education to all handicapped children between 2 and 21 years of age. Amendments to this act in 1986 (PL 99-457) encouraged states to provide early intervention services for infants and toddlers with developmental delay conditions through federal funding.

The child may require supportive care and assistance with activities of daily living. The plans for intervention need to change as the child grows and the family situation alters. Classes and special services are needed for youth and families when the adolescent with intellectual disability transitions into young adulthood.

Nursing Management

For the Child With Intellectual Disability

Nursing Assessment and Diagnosis

Nurses can help identify children with intellectual disability through history taking, observation, and developmental screening during early childhood. The history should provide information about the mental and adaptive functioning of birth parents and other family members, as intellectual disability may cluster in some families, and conditions such as fragile X syndrome are genetic in origin. The pregnancy and birth history can provide important information about the mother's alcohol and drug use during pregnancy. Be alert for a history of difficult pregnancy

A

B

Figure 28–8 **Physical therapy is an important component of medical management for many children who have intellectual disabilities. *A,* This girl, who is severely intellectually disabled and uses a wheelchair, is being positioned in a mobile prone stander, which enables her to interact in a different manner with her therapists and the environment. *B,* Physical therapists also provide outpatient care in the community to children with varying degrees of disability.**

and problems during birth. Prematurity places the child at risk of below-normal cognitive development. Frequent developmental testing during early childhood is needed for infants born prematurely. When genetic conditions in the family predispose family members to intellectual disability, assess the child carefully. Children from deprived environments or those at risk because of environmental factors such as lead poisoning (see Chapter 17) are more likely to manifest intellectual disability.

Many children with intellectual disability are not diagnosed until they reach school age, particularly if the condition is mild. Early intervention, however, can help enhance the child's functioning later. During home visits, during clinic appointments, in childcare centers, and during hospitalization, be alert for signs such as developmental delays, multiple (more than three) physical anomalies associated with a specific condition (see Table 28–8), or neurologic alterations. Developmental assessment should be part of each healthcare visit; see Chapters 7, 8, and 9 for developmental surveillance recommended at each age.

When the diagnosis of intellectual disability has been made, assess the adaptive functioning of the child and family. Perform a functional assessment of the child, including toileting, dressing, and feeding skills. Assess the child's language, sensory, and psychomotor functioning. Assess the home and community for safety hazards. Observe how the family is managing with the child. Ask about family activities that include the child, community and school attitudes and support, and care management as well as planning for the future. Assess the availability of services such as groups for parents and special education opportunities for children. Evaluate the coping skills of family members.

Several nursing diagnoses may be appropriate for the child with intellectual disability, depending on the degree, cause, and outcome of the child's condition. Some of these diagnoses relate to impairments in adaptive functioning; others relate to the impact on the family. Examples include the following (NANDA-I © 2014):

- ***Development: Delayed, Risk for,*** related to neonatal disease or condition
- ***Nutrition, Imbalanced: Less than Body Requirements,*** related to inability to ingest sufficient food
- ***Self-care Deficit: Dressing, Toileting, Bathing,*** related to developmental disability
- ***Communication: Verbal, Impaired,*** related to developmental disability
- ***Injury, Risk for,*** related to lack of understanding of environmental hazards
- ***Coping: Family, Compromised,*** related to the child's developmental variations

Planning and Implementation

Nearly all children with intellectual disability are cared for in the community. However, they may have conditions that require periodic hospitalization or frequent healthcare visits. Nursing care focuses on providing emotional support and information to family members, maintaining a safe environment, assisting the child with adaptive functioning, and fostering parental management of the child's activities. Whenever possible, the nurse uses preventive teaching to lower the risk of disability. For example, nurses can integrate teaching into care for all women about the importance of avoiding all alcohol during any times when they might become pregnant. This helps prevent fetal alcohol syndrome, especially in early pregnancy when women may not know they are pregnant.

PROVIDE EMOTIONAL SUPPORT AND INFORMATION

Family members need empathy and support both at the time of diagnosis and in the ensuing years. Parents may be in an acute or chronic state of grief over the loss of the healthy child. Encourage them to verbalize their feelings. Introducing them to parents of other children who have intellectual disabilities may help and support them as they learn how to manage the child's needs. Discuss the availability of respite care to provide parents with a break from caretaking. Other family members such as grandparents and siblings may also feel grief or guilt and should be given an opportunity to talk about their feelings.

Parents need honest information and answers to their questions about the child's condition. Reinforce information provided by genetic counselors and other healthcare professionals. Parents need to know about community resources designed to assist children with intellectual disability. As mentioned earlier, the Education for All Handicapped Children Act (PL 94-142) provides free appropriate education to all handicapped children between 2 and 21 years of age. States and local communities may provide early intervention services for infants and toddlers with disabilities. Examples of programs include the Zero to Three early intervention programs, special education preschools and schools, county health services, and respite care. Ask parents if they have questions about IEPs and refer them to Internet sources if that is helpful. Review federal and state laws and services that might be helpful to the family, and help them interpret information they find to analyze its strengths and limitations.

MAINTAIN A SAFE ENVIRONMENT

Children with intellectual disabilities require close supervision because they may not understand common hazards. Ensure safety in the hospital. Assist parents in providing safety at home and school, and teaching the child necessary skills such as pedestrian safety. Consider both physical and emotional safety. The child may be indiscriminately trusting and sometimes is at risk for physical or sexual abuse.

PROVIDE ASSISTANCE WITH ADAPTIVE FUNCTIONING

Encourage parents' efforts to maximize the child's areas of strength and identify needs related to adaptive behaviors. Refer them to resources to help with the child's impaired areas of adaptive functioning, such as communication, self-care, or social skills. During hospitalization, support parents' efforts to maintain the child's skills in toileting, dressing, and self-care by planning interventions to use the skills being taught at home.

COMMUNITY-BASED NURSING CARE

The child with intellectual disability needs ongoing care throughout childhood; interventions must be adapted as the child develops and the family's needs evolve. Parents often act as case managers for the child's care. Assist parents as necessary to acquire the skills required to coordinate the child's plan of care. Evaluate the child's needs regularly and help parents with the treatment plan as necessary. Provision of education including services such as physical or speech therapy is a primary goal. Most children with intellectual disability have an IEP designed to meet their specific learning needs. Parents, nurses, and others such as teachers and language therapists are part of the team that establishes the child's IEP. Promote optimal development and socialization. As the child reaches adolescence, education is directed toward a vocation, issues of sexuality, and the goal of independent living, when appropriate. Transition classes for adolescents with intellectual disability can teach self-care skills that may enable some to live in group homes

or other community settings. Parents need help planning for the child's future and their own retirement.

Specific guidelines for care are available for the child with Down syndrome (Bull & Committee on Genetics, 2011). These guidelines suggest times for evaluation of hearing, growth, cardiac function, and other areas designed for early identification and treatment of associated disorders. There are growth grids for children with Down syndrome, and specific topics to suggest for anticipatory guidance during healthcare visits.

Evaluation

The expected outcomes of nursing care depend on the child's needs and developmental level. Early in the diagnostic phase, desired outcomes may involve the family's understanding of the diagnosis and the child's special needs. Later outcomes may focus on the child's communication of self-help skills. Outcomes related to cognitive performance and adaptive skills may be developed during childhood. Successful transition into adulthood at the maximal level of function is the ultimate desired outcome.

Chapter Highlights

- Major treatment modes for children with mental health disorders include individual therapy, family therapy, and group therapy.
- Therapeutic strategies for treatment of children and adolescents with mental health disorders include play therapy, art therapy, cognitive behavioral therapy (CBT), visualization, and hypnosis.
- Nurses conduct mental health assessments, prevent disorders when possible, participate in intervention to treat disorders, and evaluate outcomes of treatment.
- Autism spectrum disorder is the major type of pervasive developmental disorder and is manifested by abnormal behavior, social interaction, and communication.
- Attention deficit hyperactivity disorder is characterized by developmentally altered behaviors involving inattention and hyperactivity.
- Mood disorders in childhood and adolescence are commonly manifested as depression or bipolar disorder.
- Several anxiety disorders occur in children and adolescents, most notably generalized anxiety, separation anxiety, panic, obsessive-compulsive disorder, social phobia, conversion reaction, and posttraumatic stress disorder (PTSD).
- Behavioral therapy and selective serotonin reuptake inhibitors (SSRIs) are used in treatment of anxiety; prescription drug use in children must be closely monitored.
- Suicide is a significant cause of death among youth; nurses play a key role in identifying youth at risk, instituting prevention programs, and counseling families and friends of suicide victims.
- Nurses play a role in identifying children with potential learning disabilities, referring for diagnosis, and partnering with the family to provide a positive learning experience for the child.
- Intellectual disability is subaverage intellectual and adaptive functioning, and may be caused by chromosomal, genetic, or environmental factors.
- A multidisciplinary team plans the care for children with intellectual disability and periodically evaluates the child's progress and the family's needs.

Clinical Reasoning in Action

Cooper, a 5-year-old child with autism spectrum disorder, comes into the office for his annual checkup and school immunizations of diphtheria, tetanus, and acellular pertussis (DTaP); inactivated polio vaccine (IPV); and measles-mumps-rubella (MMR). He is very combative and it takes four people to help hold him and administer the vaccines. He will be attending a special school for children with autism spectrum and related disorders. Diagnosed at 3 years old, he has never been in the hospital or had surgery. It is extremely difficult to examine him as he does not like to be touched. During prior visits in the office, Cooper has stood facing the wall and twisting his hands. He continues to be combative for most of the examination, even with the use of decreased stimuli, communication, and slow movements, but you are able to assess that his blood pressure is 95/53 mmHg. He is in the 50th percentile for both height and weight and his temperature is 99°F.

You give Cooper's mother information about local support groups for children with autism spectrum disorder and about local psychiatrists who can treat the condition with medication that helps control aggressive behavior. You also supply her with contact information for counselors in the area to help her deal with her own stress. She is appreciative of your help and support and looks forward to being able to send Cooper to school.

1. The mother has questions about the MMR vaccine and whether it causes autism. What can you tell her about that? Would you administer the vaccine today?
2. What can you tell the mother about safety issues with Cooper?
3. How can you enhance communication with Cooper when he comes into the office?

Chapter 29
Alterations in Musculoskeletal Function

OMG/The Image Bank/Getty Images

When I got the call that Douglass was in the emergency room I was so scared. I guess we're lucky it was just a broken leg. I've never had a cast. What do you need to do with it? I also wonder if it's safe for him go back to his friend's house where he broke his leg on a trampoline. Should I tell him not to use the trampoline when he heals? It's hard to decide.

—Mother of Douglass, 12 years old

Learning Outcomes

29.1 Describe pediatric variations in the musculoskeletal system.

29.2 Plan nursing care for children with structural deformities of the foot, leg, hip, and spine.

29.3 Recognize signs and symptoms of infectious musculoskeletal disorders and refer for appropriate care.

29.4 Partner with families to plan care for children with musculoskeletal conditions that are chronic or require long-term care.

29.5 Prioritize nursing interventions to promote safety and developmental progression in children who require braces, casts, traction, and surgery.

29.6 Develop a nursing care plan for fractures, including teaching for injury prevention and nursing implementations for the child who has sustained a fracture.

The musculoskeletal system helps the body protect its vital organs, support weight, control motion, store minerals, and supply red blood cells. Bones provide a rigid framework for the body, muscles provide for active movement, and tendons and ligaments hold the bones and muscles together. Therefore, alterations in musculoskeletal functioning can have a significant impact on a child's growth and development.

What concerns do parents and children have when a child has musculoskeletal conditions? Will the child need any special adaptations in the home and school? Can musculoskeletal injuries be prevented? The information in this chapter will answer these questions and enable nurses to provide effective care for children who have musculoskeletal disorders.

Musculoskeletal disorders may be congenital, such as clubfoot, or acquired, such as osteomyelitis. They may require short- or long-term management, and may be treated on an outpatient basis or require hospitalization.

Text continues on page 826

FOCUS ON:
The Musculoskeletal System

Anatomy and Physiology

The musculoskeletal system is composed of the bones and muscles; joints, the supporting structures that facilitate movement; and tendons and ligaments that connect parts of the system. Cartilage is the connective tissue precursor to bone and remains in some structures such as ears and ribs throughout life. Bone formation is a dynamic system at any age, but particularly so in children and adolescents. Children depend on a functioning musculoskeletal system to enable support and movement, which in turn ensures that exposure to various stimuli and normal development can occur.

Bones are composed of osseous or dense connective tissue; they contain an exterior shell or cortex and an inner, primarily protein, matrix (Figure 29–1). The cells covering the cortex are called lining cells or compact bone, and they protect the bone from penetration by circulating blood cells and other components of circulation; this covering is called the periosteum. The inner matrix is composed of a series of interconnected plates called cancellous, trabecular, or spongy bone. Spaces between these plates are called bone marrow, and this is the area where hematopoiesis (production and development of blood cells) occurs. In addition to the lining cells found on the bone exterior, other types of cells include osteoblasts, which synthesize and lay down bone and then attract calcium and phosphates to strengthen the bone; osteoclasts, which resorb bone in the constant process of bone formation and breakdown; and osteocytes, which are special osteoblasts that sense and respond to bone pressure and bending to direct the process of bone remodeling. The process of bone growth and remodeling is influenced by factors such as pressure (via physical activity), hormones (parathyroid hormone, glucocorticoids, insulin-like growth factor, and calcitonin), and external factors (dietary intake of calcium and phosphorus, bisphosphonate drugs, gallium, and so on).

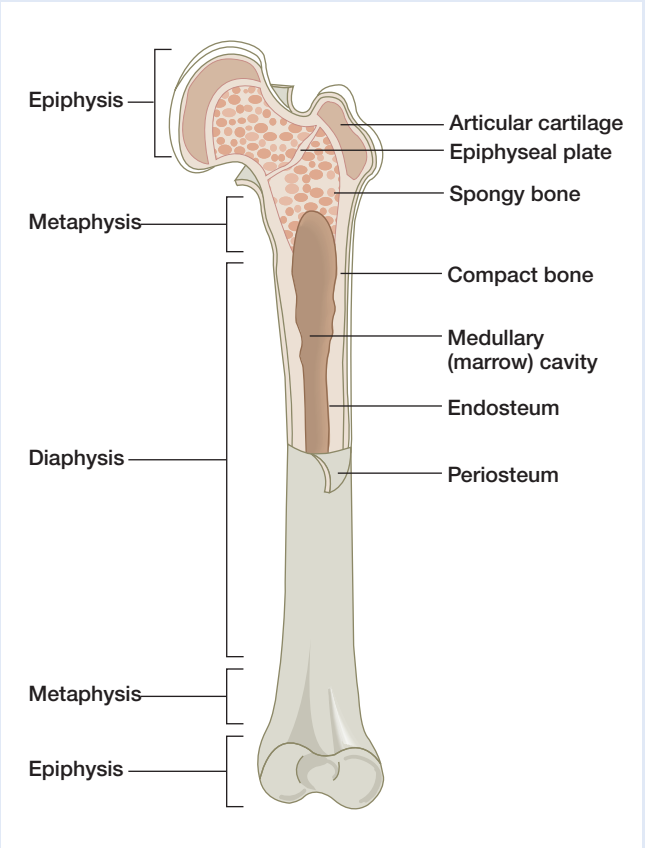

Figure 29–1 The parts of long bones.

The 206 bones of the human body include several types:

- *Long bones* such as the fibula, tibia, femur, humerus, and ulna; most childhood growth occurs in these bones
- *Short bones* such as those in the wrist and ankle
- *Flat bones* such as the skull, sternum, and ribs; the ribs retain large components of cartilage even when mature
- *Irregular bones* that have a variety of shapes and sizes, such as vertebrae, pelvic bones, and scapula

Muscles are collections of cells that can contract, causing the accompanying skeleton to move. Muscle fibers require a supply of blood and nerves and vary from small to quite large in size. Muscle cells develop in response to the stimulation of activity. Types of muscle cells include:

- *Skeletal* (striated) or *voluntary* muscles that involve the biceps, triceps, deltoid, gluteus maximus, and others
- *Smooth* (short-fibered) or *involuntary* muscles such as those in the gastrointestinal tract, lungs, and pupils of the eye
- *Cardiac* (striated, special-function) muscles that ensure the heart's constant contraction and relaxation

Muscles enable parts of the body to flex and extend, abduct and adduct, and carry out other motions (Figure 29–2). As one muscle flexes, the opposing muscle must extend to allow the movement.

Several other structures enable the musculoskeletal system to function. The joints are articulations or connections between bones. Fibrous joints provide for little movement (e.g., those in the skull), cartilaginous joints allow for slight movement (e.g., vertebral joints), and synovial joints are movable within certain limits (e.g., knee, hip, elbow, and shoulder). Joints are complex in structure and function, containing the fibrous end of the bone, synovial membrane and fluid, other sacs called bursae, and ligaments. Ligaments are tough fibers that bind the ends of bones together. Tendons are fibrous bands that connect bone to its accompanying muscles, allowing the bone to move when a muscle contracts or relaxes.

Pediatric Differences

Bones

Several differences exist between the bones of children and those of adults. Although primary centers of **ossification** (bone formation) are nearly complete at birth, a fibrous membrane still exists between the cranial bones (fontanelles). (See *As Children Grow: Sutures* in Chapter 5.) The posterior fontanelle closes

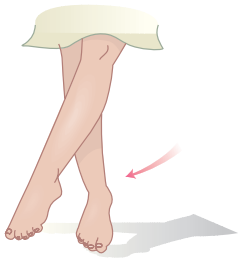
Varus
An abnormal position of a limb that involves bending inward toward the midline of the body

Valgus
An abnormal position of a limb that involves bending outward away from the midline of the body

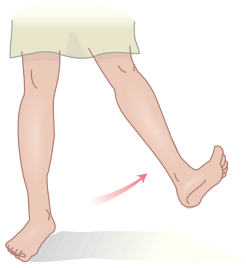
Supination
Lying on the back or placing the hand so that palm faces upward

Pronation
Lying on the stomach or placing the hand so the palm faces downward

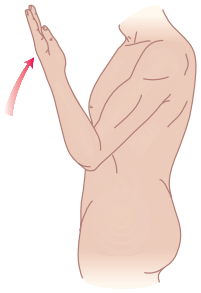
Adduction
Lateral movement of limbs toward the midline of the body



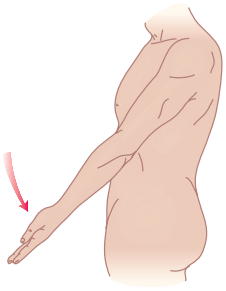
Abduction
Lateral movement of limbs away from the midline of the body



Flexion
A decrease in angle between bones forming a joint

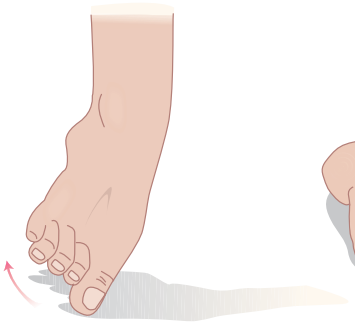


Extension
A movement that brings a limb into a straight position

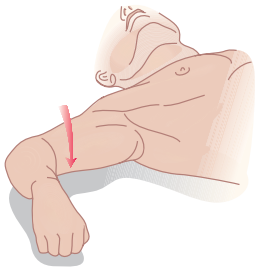


Inversion
Turning inward, usually more than normal

Eversion
Turning outward



Internal rotation
Rotation of a body part toward the midline of the body



External rotation
Rotation of a body segment away from the midline of the body

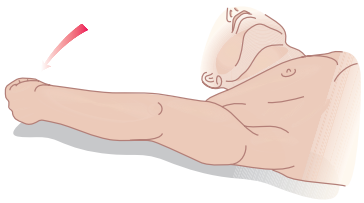


Figure 29–2 Musculoskeletal positions and joint motions.

TABLE 29–1 Diagnostic and Laboratory Procedures/Tests for the Musculoskeletal System

DIAGNOSTIC PROCEDURES	LABORATORY TESTS
Arthrogram	Alkaline phosphatase (ALP)
Bone scan	C-reactive protein (CRP)
Computed tomography (CT)	Erythrocyte sedimentation rate (ESR or sed rate)

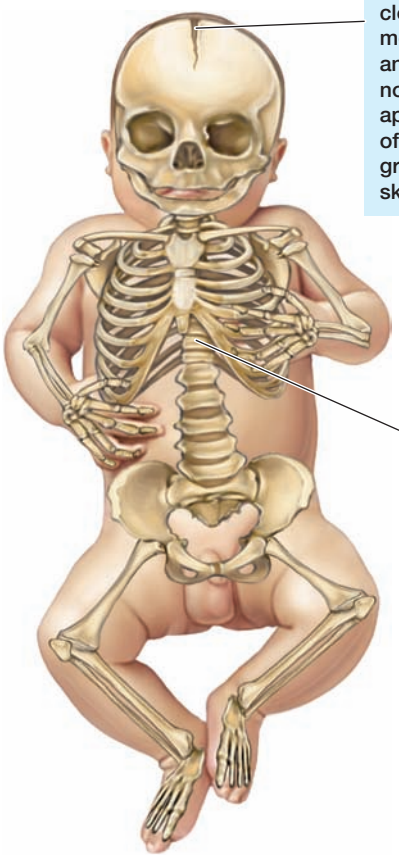
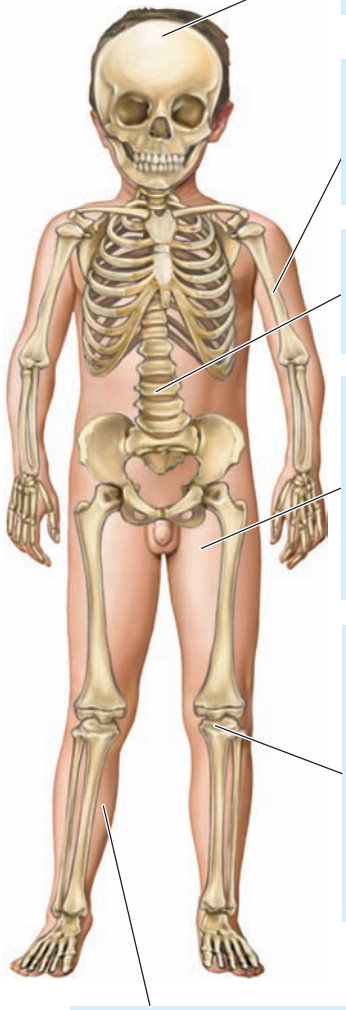
As Children Grow: **Musculoskeletal System**



A fibrous membrane still exists between the cranial bones (fontanelles). The posterior fontanelle closes between 2 and 3 months of age. The anterior fontanelle does not close until approximately 18 months of age, allowing for growth of the brain and skull.

The thoracic and sacral regions of the spine are convex curves. As the infant learns to hold up the head, the cervical region becomes concave.



Most growth of the skull occurs by 2 years of age, with the skull reaching full size by 16 years.

The long bones of children are porous and less dense than those of adults, leading to higher rates of fracture.

When the child learns to stand, the lumbar region becomes concave in shape.

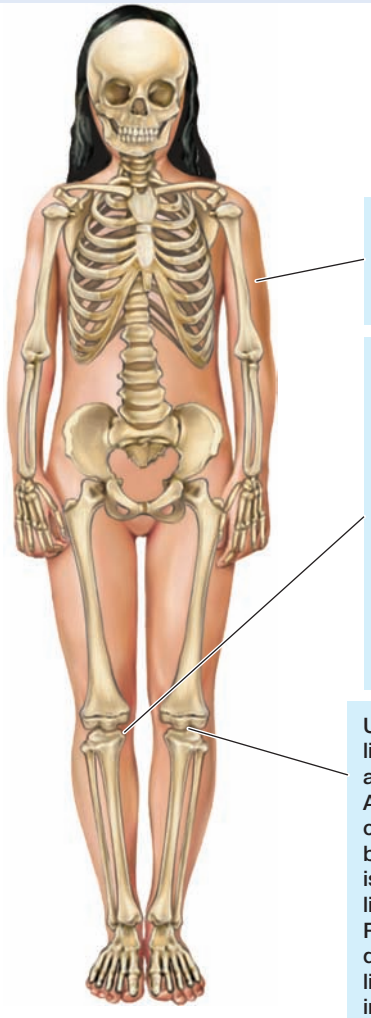
As a child grows, muscles do not increase in number, but rather in length and circumference. Muscle fibers reach maximum diameter in girls at about 10 years of age, and in boys at 14 years.

During childhood, cartilage cells at the epiphyses (an area enriched with blood cells) are replaced by osteoblasts (immature bone cells), which push the end of the bone away from the shaft and engineer the deposition of calcium within the newly formed bone.

The rapid bone growth of childhood facilitates healing after fractures, but may also lead to "growing pains" as muscles are pulled when bones grow quickly.

between 2 and 3 months of age. The anterior fontanelle does not close until approximately 7 to 19 months of age, allowing for growth of the brain and skull (National Institutes of Health, 2012a). Most growth of the skull occurs by 2 years of age, with the skull reaching full size by 16 years.

Secondary ossification occurs as the long bones grow. Cartilage cells at the epiphyses (an area enriched with blood cells) are replaced by osteoblasts (immature bone cells), which push the end of the bone away from the shaft and engineer the deposition of calcium within the newly formed bone. Calcium intake during childhood and adolescence is essential to provide adequate bone density that will prevent osteoporosis and fractures in adulthood. See Chapter 14 for a discussion of inadequate calcium intake during school age and adolescence. Because growth takes place at the epiphyseal plates, injuries to this portion of a long bone are of particular concern in young children. The rapid bone growth of childhood facilitates healing after fractures but may also lead to "growing pains," as muscles are pulled when bones grow quickly. The ends of the long bones (epiphyses) remain cartilaginous, allowing growth, until approximately age 20 years, when skeletal maturation is complete. At this time, the epiphyseal plate



Muscle strength continues to increase until about 25–30 years of age.

The ends of long bones (epiphyses) remain cartilaginous, allowing growth, until approximately age 20 years, when skeletal maturation is complete. At this time the epiphyseal plate closes, cartilage at the site is replaced by bone, and only an epiphyseal line remains.

Until puberty, both ligaments and tendons are stronger than bone. As the child ages and cartilage is replaced by bone, the resulting bone is stronger than ligaments or tendons. Rates of fractures decrease while injuries to ligaments and tendons increase.

closes, cartilage at the site is replaced by bone, and only an epiphyseal line remains.

Children and adolescents may sustain injury to the musculoskeletal system from falls, car crashes, and sports. Fractures are one type of common injury. The long bones of children are porous and less dense than those of adults. For this reason, children's bones can bend, buckle, or break as a result of a simple fall. In addition to the structural differences between the bones of children and adults, there are functional differences in the skeletal system of children. Before birth, the thoracic and sacral regions of the spine are convex curves. As the infant learns to hold up the head, the cervical region becomes concave. When the child learns to stand, the lumbar region also becomes concave. Failure of the spine to assume these final curves results in an abnormal curvature of the spine (kyphosis or lordosis).

Muscles, Tendons, and Ligaments

The muscular system, unlike the skeletal system, is almost completely formed at birth, with any remaining increase achieved in the first year of life. As a child grows, muscles do not increase in number, but rather in length and circumference. Muscle fibers reach maximum diameter in girls at about 10 years of age, and in boys at 14 years. Muscle strength continues to increase until about 25–30 years of age.

Until puberty, both ligaments and tendons are stronger than bone. When these structural differences are not recognized, a childhood fracture is sometimes mistaken for a sprain. A **sprain** is a tearing of ligaments, the structural support connecting bones, usually caused when a joint is twisted or otherwise traumatized. Tendons, which connect bones to muscles, grow in length and fibrous tissue as mechanical pressure is placed on them.

Use the *Assessment Guide* to perform a nursing assessment of the musculoskeletal system. Many diagnostic and laboratory tests are used for the musculoskeletal system. Examples can be found in Table 29–1; see Appendices D and E for more information about these tests and procedures.

Figure 29–2 reviews several terms that will be used throughout this chapter in describing the positioning of a child's limbs. See *Assessment Guide: The Child With a Musculoskeletal System Alteration.*

ASSESSMENT GUIDE | The Child With a Musculoskeletal System Alteration

Assessment Focus	Assessment Guidelines
Muscles	• Is muscle mass symmetric? • Do fine and gross motor movements correspond to developmental expectations? • Can you identify any abnormal signs such as asymmetry of movement, tenderness, masses, weakness, hypotonia, hypertonia? • Can the school-age child get up from a lying or sitting position in the usual manner? • Can you describe the child's usual daily physical activity? • Has there been a loss of ability to perform developmental milestones?

(*continued*)

Assessment Focus	Assessment Guidelines
Joints	• Are movements smooth and symmetric? • Are there any signs of tenderness, decreased range of motion, inflammation, crepitus/grinding, or masses? • Do the hips of newborns and infants manifest symmetric full range of motion? • Were there recent events of trauma such as in sports or a fall?
Bones	• Are any masses noted? • Are arms and legs the same length? • Is there a recent decrease or change in mobility, such as limping? • Are bones in alignment, or are abnormalities noted such as bowlegs or knock-knees? • Upon spinal screening, is the spine properly aligned (see screening procedure within this chapter)? • In what sports does the child participate? Is recommended protective gear worn?
Tendons and ligaments	• Do all joints move through full range of motion? • Is there any pain upon joint motion or palpation? • Are there feelings of grinding or crepitus as the joint moves? • Has there been a recent sports or other injury? • In what sports does the child participate?
Family history	• Is there a family history of disorders of the muscular or skeletal systems?

Some disorders affect other body systems as well; for example, see cerebral palsy in Chapter 27. Many musculoskeletal disorders require surgical correction, casting, or braces.

Disorders of the Feet and Legs

Metatarsus Adductus

Metatarsus adductus, the most common congenital foot deformity, is characterized by an inward turning of the forefoot at the tarsometatarsal joints (Figure 29–3). Often referred to as "intoeing," metatarsus adductus affects male and female infants equally and occurs in approximately 1 in 1000 births, with more common incidence being in first births and in families with prior cases of the disorder. It is sometimes accompanied by other problems such as developmental dysplasia of the hip (described later in this chapter) (Gilmore & Thompson, 2013; National Institutes of Health, 2012b). This condition is most likely caused by both intrauterine positioning and genetic factors. Metatarsus adductus is differentiated from other causes of intoeing, such as internal tibial torsion (more common in children ages 12 to 18 months who are learning to walk) and femoral anteversion (seen more often in preschool-age children).

Treatment depends on the degree of foot flexibility. If the foot can be readily maneuvered past the neutral position, simple exercises may correct the problem. Most cases resolve spontaneously by the time the infant is about 3 months of age. Serial casting is the treatment of choice for curvature angles greater than 15 degrees, or in cases that do not improve. The infant's feet are placed in a position as close to neutral as possible and are held secure with casts. Casts are changed weekly until the desired correction is achieved. Braces and orthopedic shoes may also be used to maintain correction after casting.

Figure 29–3 **Metatarsus adductus. This disorder is characterized by convexity (curvature) of the lateral border of the foot. The child's right foot demonstrates the disorder. Note that the forefoot turns inward and appears out of alignment with the remainder of the foot.**

Nursing Management

Reassure parents that the child's condition can be corrected. If the child's deformity is mild, teach parents simple stretching exercises to perform at each diaper change. The foot is held securely by the heel, and the forefoot is moved outward from the body with the other hand. The position is maintained for 5 seconds, and repeated 5 times at each diaper change. If casting is necessary,

provide cast care as outlined in Table 29–2 and teach parents how to care for the child in a cast at home. If metatarsus adductus persists into childhood without correction, the challenge is to find shoes that accommodate the unusual shape of the foot.

Clinical Tip

Casts are made out of plaster or fiberglass material. The former is durable and may be chosen for applications that will last for a long time. Plaster casts must be kept dry or they will deteriorate. Fiberglass casts are lighter and available in various colors and are therefore popular with children. While the outside of the cast can become moist without breakdown, the lining underside is not waterproof, so caution is still followed to preserve the cast integrity.

Clubfoot

Clubfoot is a congenital abnormality in which the foot is twisted out of its normal position. It occurs in approximately 1 to 2 in 1000 births, affects boys nearly twice as often as girls, and is bilateral in about half of affected infants (Gilmore & Thompson, 2013).

ETIOLOGY AND PATHOPHYSIOLOGY

The exact cause of clubfoot is unknown; however, several possible etiologies have been proposed. Some authorities believe abnormal intrauterine positioning causes the deformity. Others suspect neuromuscular or vascular problems as causes. There is a genetic component in some cases because the risk of having a second child with clubfoot when an earlier child is affected is 25% (Gilmore & Thompson, 2013).

CLINICAL MANIFESTATIONS

A clubfoot (talipes equinovarus) involves three areas of deformity: The midfoot is directed downward (**equinus**), the hindfoot turns inward (**varus**), and the forefoot curls toward the heel (adduction) and turns upward in partial supination. Muscles, tendons, and bones are all involved in the abnormality, and it cannot be corrected by exercise. Most children have this combination of findings. The foot is small with a shortened Achilles tendon. Muscles in the lower leg are atrophied, but leg lengths are generally normal (see *Pathophysiology Illustrated: Clubfoot*).

TABLE 29–2 Nursing Care of the Child in a Cast

- A plaster cast takes anywhere from 24–48 hr to dry. When handling the wet cast, be gentle and use the palms of your hands, as fingertips can indent plaster and create pressure areas.
- After the cast is applied, elevate the extremity on a pillow above the level of the heart. Elevation helps reduce swelling and increases venous return.
- If the cast is applied after surgery, there may be drainage or bleeding through the cast material. Circle the stain and note the date and time on the cast to provide a way to assess the amount of fluid lost.
- Assess the distal pulses, and check the fingers and toes for color, warmth, capillary refill, and edema. Assess sensation as well as movement. Any deviation from normal may indicate nerve damage or decreased blood supply.
- During the first 24 hr, check the casted extremity every 15–30 min for 2 hr, then every 1–2 hr thereafter. The skin should be warm. It should blanch when slight pressure is applied and then return to its normal color within 3 sec (**A**). For the next 2 days, assess the casted extremity at least every 4 hr.

A

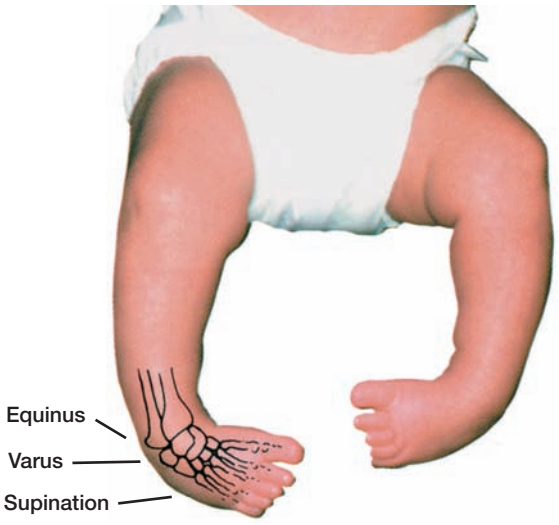
- Check the edges of the cast for roughness or crumbling. If necessary, pull the inner stockinette over the edge of the cast and tape in place.
- The rough edges of the cast may also be alleviated by "petaling." This is done by securing tape or padding to the inside of the cast and pulling it over the edge, covering the jagged or broken pieces of plaster, and securing it to the outer surface of the cast (**B, C, D**). Moleskin may be used on the cast as well.
- Keep the cast as clean and dry as possible. Cover the cast with plastic when the child bathes. Never leave the child alone to bathe, and discard the plastic safely so that the child cannot reach it because of suffocation hazard.
- The skin under the cast may itch; however, do not use powders or lotions near the edges or under the cast as they can cause skin irritation.
- Be sure that children do not put small objects between the casts and their extremities; that can cause skin irritation as well as neurovascular compromise.

B

C

D

Pathophysiology Illustrated: **Clubfoot**



Bilateral clubfoot deformity. Parents of a child with clubfoot will have many questions. Can the condition be treated? Will the child be able to walk normally after surgery? Will they need help caring for the infant? How much will surgery and other care cost? Will any subsequent children have a clubfoot?

CLINICAL THERAPY

Diagnosis is made at birth on the basis of visual inspection. Radiographs are used to confirm the severity of the condition.

Early treatment is essential to achieve successful correction and reduce the chance of complications. Serial casting is the treatment of choice. Casting should begin as soon as possible after birth. Timing is critical because the short bones of the foot, which are primarily cartilaginous at birth, begin to ossify shortly thereafter. The foot is manipulated to achieve maximum correction first of the varus deformity and then of the equinus deformity. A long leg cast holds the foot in the desired position (Figure 29–4). The cast is changed every 1 to 2 weeks. This regimen of manipulation and casting continues for approximately 8 to 12 weeks until maximum correction is achieved. If the deformity has been corrected, the child may begin wearing a splint or reverse cast (shaped so that the foot turns outward away from the body instead of the normal inward turn) or corrective shoes to maintain the correction. If the deformity has not been corrected, surgery is required. Casting holds the foot in position until surgery is performed.

Figure 29–4 **This girl has a long leg cast, which was applied after surgery to correct her clubfoot deformity.**

The age at which a child undergoes clubfoot surgery varies among surgeons. However, most children have surgery between 3 and 12 months of age. The one-stage posteromedial release procedure, which involves realignment of the bones of the foot and release of the constricting soft tissue, is most common. The foot is held in the proper position by one or more stainless steel pins. A cast is then applied with the knee flexed to prevent damage to the pin and to discourage weight bearing. Casting continues for 6 to 12 weeks. The child may then need to wear a brace or corrective shoes, depending on the severity of the deformity and the surgeon's preference (Gilmore & Thompson, 2013).

More severe cases or those not corrected in infancy may require more than one surgery to correct the foot.

Nursing Management

For the Child With Clubfoot

Nursing Assessment and Diagnosis

Nursing assessment, which begins at birth and continues throughout the child's subsequent outpatient casting visits and hospitalization for surgery, includes taking a genetic and birth history, performing a physical examination (including position and appearance of the foot), and assessing the child's motor development and family's coping mechanisms. Because parents will need to bring the child for frequent cast changes, assess access to transportation and other arrangements needed for these visits.

Among the nursing diagnoses that might apply to the child with a clubfoot deformity are the following (NANDA-I © 2014):

- ***Mobility: Physical, Impaired,*** related to prescribed movement restriction of cast
- ***Skin Integrity, Risk for Impaired,*** related to cast
- ***Parenting, Impaired,*** related to birth of a child with a physical defect
- ***Health Maintenance, Ineffective,*** related to lack of information about deformity, treatment, and home care

Planning and Implementation

Nursing management involves providing emotional support, educating the family about home care of the child in a cast and the importance of keeping appointments at the outpatient facility for cast changes, preparing the family for the child's hospitalization if surgery is to occur, and providing postsurgical care.

PROVIDE EMOTIONAL SUPPORT

Clubfoot affects both the child and the family. The child's foot deformity is upsetting to parents, and they need emotional support to allay their fears. Helping parents understand the condition and its treatment is essential.

Families Want to Know

Care of the Child With a Cast

Skin Care

- Check the skin around the cast edges for irritation, rubbing, or blistering. The skin should be clean and dry.
- Cleanse the skin just under the cast edges and between the toes or fingers with a cotton-tipped applicator and rubbing alcohol. Avoid using lotions, oils, and powders near the cast as they may cause caking.
- Avoid poking sharp objects down inside the cast as this may result in sores.

Cast Care

- Keep the cast dry. Protect plaster with a cast shoe, thick sock, or sling.
- Allow a new, wet cast to air-dry for 24 hours. Raise it on pillows just above heart level to prevent swelling.
- Begin walking on a leg cast only when the physician gives permission.

Be Alert for Possible Complications

- Toes or fingers should be pink, not blue or white.
- Skin should be warm and the tips of the toes should blanch when pinched.

Notify Your Healthcare Provider if Any of the Following Occurs

- Unusual odor beneath the cast
- Burning, tingling, or numbness in the casted arm or leg
- Drainage through the cast
- Swelling or inability to move the fingers or toes
- Slippage of the cast
- Cast cracked, soft, or loose
- Sudden unexplained fever
- Unusual fussiness or irritability in an infant or child
- Fingers or toes that are blue or white
- Pain that is not relieved by any comfort measures (e.g., repositioning or pain medication)

Source: Courtesy of Shriners Hospital for Children, Spokane, WA.

Promote bonding by encouraging parents to hold and cuddle the child and to take an active role in the child's care. Explain that, with treatment, the child is expected to grow and develop normally.

PROVIDE CAST AND BRACE CARE

Routine cast care, earlier outlined in Table 29–2, is important to ensure skin and neurovascular integrity. After serial casting is complete, or after surgery, the child may progress to wearing a brace or special shoe for 6 to 12 months. Braces should fit snugly but should not interfere with neurovascular function. Before the child begins to wear a brace, check the skin for any areas of redness or breakdown. Give parents guidelines for brace wear. Emphasize that proper skin care is essential. If skin redness develops, arrange to have the fit of the brace evaluated and modified if necessary.

PROVIDE POSTSURGICAL CARE

Routine postoperative care after surgical correction includes neurovascular status checks every 2 hours for the first 24 hours and observing for any swelling around the cast edges (see Table 29–2). Apply ice bags to the foot, and keep the ankle and foot elevated on a pillow for 24 hours. This promotes healing and helps with venous return. Check for drainage or bleeding. Administer pain medication routinely for 24 to 48 hours. Popliteal or epidural blocks may be placed during surgery and used in the immediate postsurgical period for pain control. Monitor these blocks for effectiveness and any undesired effects. (See Chapter 15 for detailed instructions on pain management.)

SAFETY ALERT!

The most serious complication of a cast is the obstruction to normal blood flow and nerve innervation. Monitoring of the child's distal extremity is important to identify this complication. If color, temperature, or other abnormalities are present, inform the nursing supervisor or physician immediately. Have a cast cutter readily available on the unit in case the cast needs to be removed. See the section on compartment syndrome later in this chapter.

DISCHARGE PLANNING AND HOME CARE TEACHING

Give parents written instructions for care of the child with a cast (see *Families Want to Know: Care of the Child With a Cast*). In addition, assist them in the following ways:

- Demonstrate the use of a sponge bath to protect the cast from water breakdown. Have parents contact the healthcare provider if the cast gets wet with water or urine.
- Discuss options for clothing that accommodate a cast, for example, one-piece snap suits or sweatpants.

Families Want to Know

Guidelines for Brace Wear

- Braces should be as comfortable as possible and the child should have adequate mobility while wearing the brace.
- Begin wearing the brace for periods of 1 to 2 hours and then progress to 2 to 4 hours.
- Check the skin at 1- to 2-hour intervals initially, then every 4 hours once skin has been clear for several days. If redness is apparent, leave the brace off and allow the skin to clear. If breakdown has occurred, the brace cannot be replaced until healing is complete. (See Chapter 31 for a discussion of pressure ulcers.)
- Always have the child wear a clean white sock, T-shirt, or other thin white liner beneath the brace. Be sure the liner is wrinkle-free under the brace. Avoid using powders or lotions that can cause skin to break down. Toughen any sensitive areas using alcohol wipes 3 to 4 times daily.
- Reapply the brace when the skin returns to its normal color.
- Return to the orthotic specialist or other specified healthcare provider if discomfort or red areas persist or if the brace needs adjustment or repair or is outgrown.
- Check the brace daily for rough edges.

- Discuss potential safety hazards that may result from awkward positioning. Be sure the child is properly situated in a car safety seat for the trip home.
- Provide resources for strollers and other equipment that will support the cast so it does not hang down during the baby's activities.
- Suggest that parents try to place toys within the child's reach, since the movements of a child in a cast may be slowed.

Evaluation

Expected outcomes of nursing care include maintenance of skin integrity, recovery without complications after surgery, normal developmental progression of the child, and demonstrated parental knowledge of care of braces or casts, as needed.

Genu Varum and Genu Valgum

Genu varum (bowlegs) is a deformity in which the knees are widely separated while the ankles are close together and the lower legs are turned inward (varus). In genu valgum (knock-knees), the knees are close together and the lower legs are directed outward (valgus) (Figure 29–5). Chapter 5 discusses the assessment of bowlegs and knock-knees in children.

At certain stages of a child's development, the appearance of bowlegs or knock-knees is normal. Until 2 to 3 years of age, the knees are normally bowed, showing varus alignment, and by 4 to 5 years, some knock-knee or valgus alignment is common. However, the persistence of knock-knees beyond the age of 4 to 5 years necessitates further evaluation. The most common pathologic causes of bowed legs are Blount disease and rickets (see Chapter 14). Blount disease is characterized by abnormal growth on the medial side of the proximal tibia, which causes an increasing varus deformity. It is believed to be caused by increasing compression forces across the medial knee; is more common in overweight, Black, and female children; and has been associated with low serum vitamin D levels (Sabharwal, 2015). Rickets is a result of inadequate bone mineralization, usually caused by a deficiency of calcium, vitamin D, or both. Because the bones are decalcified or softened, long bones such as those in the legs may bend into a bowed position. Occasionally, rickets is congenital and is caused by an X-linked autosomal dominant or recessive gene with the chromosomal location Xp22.31-p21.3. It results in an enzyme deficiency of alkaline phosphatase, which in turn leads to excessive inhibitors of bone mineralization. This type of rickets is rare and is called *familial hypophosphatemic rickets (FHR).*

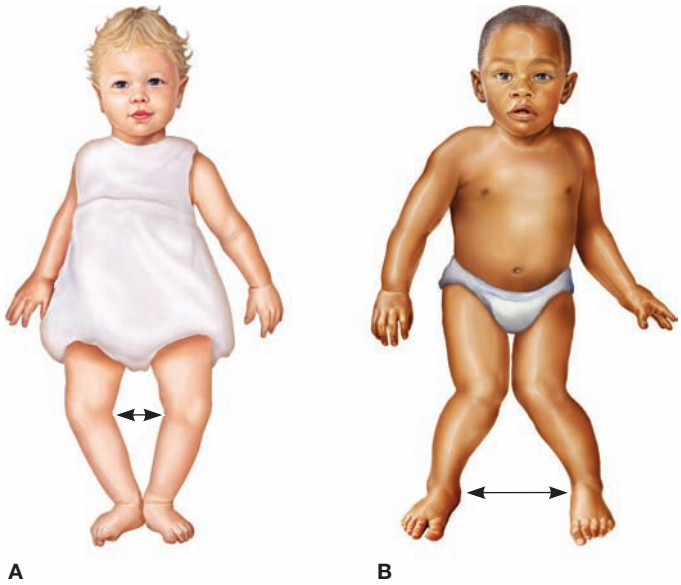


Figure 29–5 **Genu varum and genu valgum. *A*, Genu varum, or bowlegs. The legs are bowed so that the knees are far apart as the child stands. *B*, Genu valgum, or knock-knees. Note that the ankles are far apart when the knees are together.**

Measurements, radiographs, arthrography (joint radiograph), magnetic resonance imaging (MRI), and computed tomography (CT) imaging may be used for accurate diagnosis. Braces are often used to correct mild deformities that could worsen as the child grows. Braces for bowlegs are worn at night; those for knock-knees both day and night. Duration of brace wear is determined by the severity of the deformity, which is usually evaluated by radiographs. If the deformity continues to worsen, surgery is necessary. Surgery is common in treatment of Blount disease. An **osteotomy** (cutting of the bone) is performed and the tibiofemoral angle surgically corrected. The child is then placed in a cast for approximately 6 to 10 weeks, or until completely healed (Birch, 2013). When dietary rickets is the cause of varus deformity, supplementation with calcium and vitamin D is needed. FHR is treated with calcium and phosphorus in 5 to 6 daily doses.

Nursing Management

Reassure parents that bowlegs and knock-knees are usually a normal part of a child's growth and development. These conditions often resolve spontaneously and need no treatment other than continued observation.

Nursing care focuses on educating the parents and child about the condition and its treatment. Give the child and family guidelines for brace wear and maintenance (see *Families Want to Know: Guidelines for Brace Wear*).

Disorders of the Hip

Developmental Dysplasia of the Hip

Developmental dysplasia of the hip (DDH) refers to a variety of conditions in which the femoral head and the acetabulum are improperly aligned. These conditions include hip instability, **dislocation** (displacement of the bone from its normal articulation with the joint), **subluxation** (in this instance, a partial dislocation), and acetabular **dysplasia** (abnormal cellular or structural development leading to instability) (Schwend, Shaw, & Segal, 2014). In the past, DDH was referred to as *congenital dislocated hip (CDH).* The revised name of the disorder emphasizes that many cases of dislocation, subluxation, and dysplasia occur well after the neonatal period and involve more than a simple dislocation.

One in 100 newborns has hip instability, while dislocation occurs in 1.5 to 20 in 1000 births, depending on the studies examined. The condition affects girls four times as often as boys. It is unilateral in 80% of affected children, and the left hip is affected three times as often as the right (Roof, Jinguji, & White, 2013).

ETIOLOGY AND PATHOPHYSIOLOGY

Although the exact cause of DDH is unknown, genetic factors appear to play a role. The condition is 20 to 50 times more common in first-degree relatives of an infant with the condition than in the general population. If one child of a set of identical twins has DDH, the other twin is affected 30% to 40% of the time. Some types of DDH are linked to early gestational events at 12 and 18 weeks' gestation, as the lower limbs rotate and surrounding muscles develop. On the other hand, milder cases may be influenced by mechanical forces in the last month of pregnancy such as breech position, oligohydramnios, or fetal size, and can occur after birth as the hip assumes an extended rather than flexed posture (National Institutes of Health, 2013). The left hip is involved more often than the right hip as a result of intrauterine positioning of the left side of the fetus against the mother's sacrum. Maternal estrogen may cause laxity of the hip joint and capsule, leading to joint instability, especially in female infants who respond to these estrogen levels. Carrying infants with legs predominantly in extended position rather than with hips flexed may also be associated with DDH.

Figure 29–6 **Common signs of developmental dysplasia of the hip (DDH). The asymmetry of the gluteal and thigh skinfolds is easy to see in this child with DDH.**

CLINICAL MANIFESTATIONS

Common signs and symptoms of DDH include limited abduction of the affected hip, asymmetry of the gluteal and thigh skinfolds, and telescoping or pistoning of the thigh (Figure 29–6). The older child with untreated DDH walks with a significant limp, which results from telescoping of the femoral head into the pelvis. The longer the disorder goes untreated and the more pronounced the clinical manifestations become, the more difficult the treatment.

CLINICAL THERAPY

From 60% to 80% of hip abnormalities noted in infants resolve by 2 months of age, so practitioners use care and caution in diagnosing DDH. However, only 15% to 25% of infants have known risk factors for the disorder. Therefore, the Pediatric Orthopaedic Society of North America recommends that all infants and young children should be screened for DDH until walking is well established at about 1 to 2 years of age (American Academy of Orthopaedic Surgeons [AAOS], 2014a; Roof et al., 2013). Physical examination reveals an Allis sign (one knee lower than the other when the knees are flexed) and positive Ortolani and Barlow maneuvers in babies under 8 to 12 weeks of age. Refer to Chapter 5 for a discussion of the assessment of hip dysplasia in newborns and infants. Radiographs are generally not reliable until approximately 4 months of age because the pelvis in a newborn is still primarily cartilaginous. Before 4 months of age, ultrasonography may be useful for diagnosis. Family history of DDH and a female baby in the breech position necessitate careful evaluation (AAOS, 2014a).

Treatment plans vary according to the child's age. For infants younger than 3 months, the Pavlik harness is the most commonly used method for hip reduction (Figure 29–7). The Pavlik harness is a dynamic splint—a splint that allows movement. It ensures hip flexion and abduction and does not allow hip extension or adduction. For infants older than 6 months of

Figure 29–7 **The most common treatment for DDH in a child under 3 months is a Pavlik harness. A shirt should be worn under the harness to prevent skin irritation. (It was omitted for clarity in this photograph.)**

Figure 29–8 **Surgery followed by spica cast application is commonly used in treatment of DDH.**

age, surgery with closed reduction is generally performed (positioning of the head of the femur into the acetabulum without an incision of the skin) followed by the application of a spica cast (Figure 29–8). Surgery may be preceded by a course of Bryant traction to facilitate stretching of the tissues that will promote positive surgical outcomes. In children over 18 months of age, open or closed reduction surgery and casting are usually necessary and bracing may also be required.

Early screening, detection, and treatment enable most affected children to attain normal hip function. A late diagnosis results in a lowered prognosis for full function.

Nursing Management

For the Child With Developmental Dysplasia of the Hip

Nursing Assessment and Diagnosis

Assessment for DDH begins at birth and continues through all health promotion visits during the first 2 years of life. The family history or birth data may indicate a high-risk infant. Instructions for performing the physical examination to assess the infant for DDH are provided in Chapter 5. Once treatment begins, assessments are performed based on risks of the treatment. Assess the skin of the child in traction or a cast every few minutes in the immediate postoperative period, progressing to once or twice daily at home. Include respiratory and circulatory assessments when the child is immobilized. Ongoing assessment of the child's growth and development is needed. Weigh the child in a cast once the cast is dry so a baseline casted weight can be used for comparison while the cast remains in place.

Several nursing diagnoses that may apply to the child with DDH include the following (NANDA-I © 2014):

- ***Mobility: Physical, Impaired,*** related to prescribed movement restriction (Pavlik harness, traction, spica cast, brace)
- ***Skin Integrity, Risk for Impaired,*** related to irritation from harness straps or skin traction
- ***Urinary Elimination, Impaired or Constipation,*** related to immobility caused by treatment
- ***Nutrition, Imbalanced: Less than Body Requirements,*** related to decreased appetite
- ***Development: Delayed, Risk for,*** related to limited mobility and potential decreased exposure to stimulation
- ***Knowledge, Readiness for Enhanced (Parental),*** related to lack of information about disease process and treatment

Planning and Implementation

The infant with DDH is often cared for at home and in outpatient facilities. If surgery is performed, the child is hospitalized for surgery and the immediate postoperative period. Nursing care varies according to the medical treatment and the child's age. Management includes maintaining traction, if ordered; providing cast care; preventing complications resulting from immobility; promoting normal growth and development; and teaching parents about the condition and care (e.g., management of a cast or a Pavlik harness). Because treatment may interfere with the child's normal movement, the treatment plan should take into consideration the age and developmental stage of the child in order to substitute activities to stimulate development.

PROVIDE CAST CARE AND CORRECT HARNESS ALIGNMENT

The principles of routine cast care presented in Table 29–2 apply to the care of spica casts. Special techniques should be used to help keep the cast clean and dry in children who are not toilet trained. Female and male urinals can be used for older children. Use a plastic lining to protect the cast edges during elimination for older children and use a small disposable diaper to cover the perineum in babies, tucking edges beneath the cast. Be sure to change the diaper frequently to prevent soiling of the cast.

The child in a Pavlik harness will have the harness applied in the healthcare facility. Parents need instructions on maintaining the child in the harness at all times. Return visits will be scheduled to ensure proper fit, maintenance of hip position, and skin condition.

PREVENT COMPLICATIONS RESULTING FROM IMMOBILITY

Immobilization from traction or a cast can cause alterations in physiologic functioning. To prevent complications:

- Assess breathing patterns and lung sounds frequently for congestion or respiratory compromise.
- Perform skin and neurovascular assessments approximately every 2 hours.
- Use adequate padding and skin wrapping to avoid placing pressure on the popliteal space. Such pressure could lead to nerve damage.
- For the child in a cast, change the child's position every 2 to 3 hours while awake to help avoid areas of pressure and promote increased circulation. The child can be placed either prone or supine or positioned on the floor and supported with pillows.
- Help prevent skin irritation and breakdown in the child with a cast. Use moleskin to protect from rough edges. Place tape around the perineal opening of the cast to prevent soiling.
- Increase fluids and fiber in the child's diet, as a change in bowel or bladder status is commonly associated with immobility.

Families Want to Know

Transporting the Child With Orthopedic Devices

The American Academy of Pediatrics and the National Center for the Safe Transportation of Children with Special Health Care Needs have established guidelines for transporting children with special healthcare needs:

- Riding in the rear seat is preferable.
- If the front seat must be used, the front passenger airbag should be disconnected. The National Highway and Traffic Safety Administration provides information and assistance (1-888-327-4236 or www.nhtsa.dot.gov) on how to make the disconnection.
- Use only car seat transport systems approved for use with children who have special needs.
- Install and use seats as instructed. Never alter a car safety seat to transport a child.
- Move a child from a wheelchair or other special device to the vehicle safety seat whenever this is reasonable.
- Pieces of medical equipment required during transportation (such as monitors or oxygen) or that are being transported with the child (such as wheelchair or walker) should be secured to the floor of the vehicle.
- If the child is transported by school bus, follow state and federal recommendations for school bus transportation of children with special needs.
- Keep a cellular phone and emergency equipment in the vehicle.

Source: Data from American Academy of Pediatrics, Committee on Injury and Poison Prevention. (1999, reaffirmed 2013). Transporting children with special health care needs. *Pediatrics, 104*, 988–992 (original policy); *Pediatrics, 132*, e281–e282 (reaffirmation).

- If permitted by physician orders, release the child from traction for meals and daily care. The time out of traction should not exceed 1 hour per day. Encourage parents to hold and cuddle the child at this time to promote comfort and bonding.

PROMOTE NORMAL GROWTH AND DEVELOPMENT

Engage the child in activities that stimulate the upper extremities and all five senses. Provide stimulating toys such as stacking blocks, brightly colored mobiles, soft balls, or musical toys. Position toys within the child's reach and interact with the child as much as possible. See Chapter 11 for specific recommendations for stimulating activities.

DISCHARGE PLANNING AND HOME CARE TEACHING

Teach parents how to care for a child in traction or a spica cast at home. Family members' active participation in the child's daily care during hospitalization gradually increases their confidence in their ability to provide care once home. Identify and address home care needs well in advance of discharge. Before discharge, be sure the parents have:

- Information about general cast care (see Table 29–2), positioning, bathing, toileting, and age-appropriate diversional activities. Include body mechanics for the adults moving the child.
- Knowledge of the importance of performing neurovascular checks and reporting any abnormalities immediately. Teach them circulation, motion, and sensitivity checks.
- An understanding that the bar between the legs on the cast is not to be used for holding or turning the child. The bar is used to position the legs at the proper distance; using it to lift can cause the cast to fracture, weaken, or disintegrate.
- Information on feeding the child.
- Safety teaching to minimize chance of injury to a casted child.
- Instruction about types of toys that are age appropriate and measures to prevent them from being placed into the cast (a T-shirt should be placed over the cast, covering its edges).
- Appropriate referrals for periodic assessment by a visiting nurse or home health nurse.
- Family resources to care for the child.

Before discharge, have parents demonstrate how to dress and feed a child in a spica cast. Ensure that safe travel arrangements have been made for the day of discharge. Help parents get an appropriate car safety seat in advance of discharge. Encourage parents to let the child interact with other children at home, and to provide the child in a cast with similar opportunities for play and social activities.

COMMUNITY-BASED NURSING CARE

Have parents of an infant in a Pavlik harness demonstrate care of the infant while in the harness. Teach family members about daily care (bathing, dressing, and feeding) of the infant. The harness is worn full time; instructions generally include sponge bathing while it is in place, although some physicians may allow it to be removed briefly each day for bathing. One shoulder strap is removed at a time to change a T-shirt while the legs are held in proper position. The hips and buttocks should be supported carefully in the abducted position at all times. Demonstrate how to feed the infant in an upright position to maintain abduction and how to change a diaper without removing the harness.

Instruct the parents of an infant with a harness or a child in a cast to look for any reddened or irritated areas near the harness or cast edges and to check toes frequently for proper circulation. Frequent repositioning reduces the risk of pressure sores or circulatory compromise. The infant should wear an undershirt and socks under the harness to prevent rubbing of the skin.

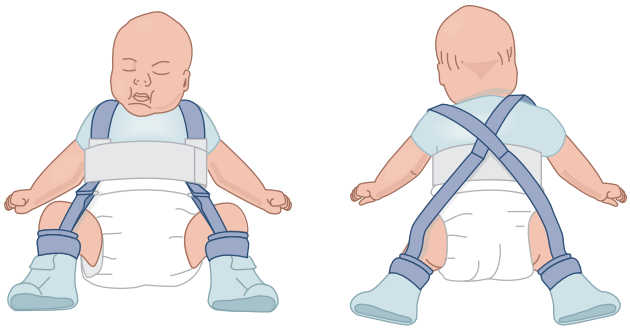
Safety precautions are important as the child will not have normal mobility. Parents will need to use a specially designed car seat that accommodates the child with abducted hips. Strollers and cribs should provide sufficient room to protect the legs from injury and to prevent hip adduction.

Families Want to Know

Guidelines for Pavlik Harness Application and Fitting

1. Position the chest halter at nipple line and fasten with Velcro.
2. Position the legs and feet in the stirrups, being sure the hips are flexed and abducted. Fasten with Velcro.
3. Connect the chest halter and leg straps in front.
4. Connect the chest halter and leg straps in back.

The harness is usually worn constantly, with removal only for bathing. Clinic visits every 1–2 weeks check for proper fit and skill condition.



Evaluation

Expected outcomes for nursing care of the child with developmental dysplasia of the hip include the following:

- The skin remains intact.
- The child has no complications due to immobility.
- Parents demonstrate adequate knowledge regarding the condition, treatment, and necessary home care.
- A safe environment is maintained for the child.
- The child regains normal mobility.

Legg-Calvé-Perthes Disease

Legg-Calvé-Perthes disease (or simply Perthes disease) is a self-limiting condition in which there is avascular necrosis of the femoral head. The disease occurs in approximately 1 in 12,000 children and affects boys 4 times more often than girls. It usually occurs between the ages of 2 and 12 years, with an average age of 7 years at onset. The disease can be unilateral or bilateral (Kannu & Howard, 2014; Perry & Hall, 2011).

ETIOLOGY AND PATHOPHYSIOLOGY

The necrosis associated with Legg-Calvé-Perthes disease results from an interruption of the blood supply to the femoral epiphysis. How and why this occurs is not completely understood, but several predisposing factors have been identified. A coagulation system disorder causes repeated vascular interruptions to the proximal femur. Disturbed blood supply to the epiphyseal plate of the femoral bone is noted, leading to necrosis of the femoral head. The incidence of the condition is increased in families with a history of the disease, which suggests that genetic factors may play a role. In 17% of cases, onset of the disease is preceded by a mild traumatic injury, and 10% of children affected have a history of breech birth (Mazloumi, Ebrahimzadeh, & Kachooei, 2014). Trauma may cause a subchondral fracture and resultant synovitis, which in turn causes pressure that occludes the blood supply. Children with Legg-Calvé-Perthes disease often have delayed skeletal maturation, increased thyroid levels, and low somatomedin C (insulin-like growth factor). It is more common in those with low birth weight, increased parental age, and exposure to environmental tobacco smoke (Mazloumi et al., 2014).

CLINICAL MANIFESTATIONS

Legg-Calvé-Perthes disease progresses through four distinct stages, over a period of 1 to 4 years, after the original insult (usually unidentified) occurs (Table 29–3). Early symptoms of Perthes disease include a mild pain in the hip or anterior thigh and a limp, which are aggravated by increased activity and relieved by rest. The child favors the affected hip and limits hip movement to avoid discomfort.

Developing Cultural Competence **Legg-Calvé-Perthes Disease**

Legg-Calvé-Perthes disease is most common among White, Chinese, and Japanese children. It is less common among African Americans, Native Americans, and East Asians. This suggests a genetic link to the disease. However, Legg-Calvé-Perthes disease is most common in children from low socioeconomic backgrounds, suggesting an environmental and/or intrauterine connection (Mazloumi et al., 2014; Perry & Hall, 2011).

As the disease progresses, range of motion becomes limited and weakness and muscle wasting develop. The affected thigh is 2 to 3 cm (0.8 to 1.2 in.) smaller than the unaffected thigh. Prolonged hip irritability may produce muscle spasms and increased pain. This period of the disease varies from 1 to 4 years. Gradually, revascularization begins and pain decreases.

CLINICAL THERAPY

Because the child's initial symptoms are mild, parents often do not seek medical attention until symptoms have been present for several months. Diagnosis is made using standard anteroposterior and frog-leg radiographs. However, radiographs taken

TABLE 29–3 Clinical Manifestations of Legg-Calvé-Perthes Disease

STAGE	CLINICAL MANIFESTATIONS
Prenecrosis	An insult causes loss of blood supply to the femoral head.
I—Necrosis	Avascular stage (3–6 months); the child is asymptomatic, bone radiographs are normal, and the head of the femur is structurally intact but avascular.
II—Revascularization	Period of 1–4 years characterized by pain and limitation of movement. Bone radiographs show new bone deposition and dead bone resorption. Fracture and deformity of the head of the femur can occur.
III—Bone healing	Reossification takes place; pain decreases.
IV—Remodeling	The disease process is over, pain is absent, and improvement in joint function occurs.

Figure 29–9 **Although the Toronto brace may seem formidable for a child to wear, you can see by this photograph that, as usual, children adapt quite well to it.**

early in the course of the disease may be normal or show vague widening of the cartilage space. Bone scans, MRI, and arthrography may be used in diagnosis. Laboratory studies of the blood, such as white blood cell count, help to rule out inflammatory synovitis of the hip. Protein C, protein S, and APC-R (resistance to activated protein C) may sometimes be performed to evaluate if a coagulation abnormality is present (de Sanctis, 2011; Milani & Dobashi, 2011).

Medical management and prognosis depend on the degree of femoral involvement. Early detection is important. The desired outcome is a pain-free hip that functions properly. To promote healing and prevent deformity, the femoral head must be contained within the hip socket until ossification is complete. This can happen only if the hips remain in an abducted position. At the beginning of treatment, traction can be used to maintain the hips in an abducted and internally rotated position. Once abduction is accomplished, treatment consists of Petrie (leg abduction) casting, or surgical soft-tissue releases such as adductor tenotomy, followed by bracing. Toronto (Figure 29–9) and Scottish Rite braces are most commonly used. Prognosis is good if the femoral head can be contained long enough for proper healing to occur. Severe disease may be treated by surgery to release adductor muscles, treat the acetabulum or femur, and restore range of motion. Children with untreated disease or those diagnosed late in the disease process occasionally develop osteoarthritis, leg length discrepancy, or hip dysfunction later in life (Nakamura et al., 2015).

Nursing Management

For the Child With Legg-Calvé-Perthes Disease

Nursing Assessment and Diagnosis

Suspect Legg-Calvé-Perthes disease in any child, especially a boy 2 to 12 years of age, who complains of hip discomfort accompanied by a limp. The school nurse may be the first person to observe the child with symptoms of Legg-Calvé-Perthes disease. The child may complain of pain and have to rest during physical education classes. Refer the child to the healthcare provider immediately. Question the child who has an apparent limp about pain, and assess the child's range of motion. Ask if the child injured the hip at some time in the past.

Nursing diagnoses, which center on altered activities and compliance, might include the following (NANDA-I © 2014):

- ***Mobility: Physical, Impaired,*** related to restriction of brace or cast
- ***Injury, Risk for,*** related to potential complications resulting from noncompliance with the treatment regimen
- ***Activity, Deficient Diversional,*** related to forced inactivity
- ***Body Image, Disturbed,*** related to brace

Planning and Implementation

Children with Legg-Calvé-Perthes disease often receive all of their treatment at home. Helping the child and family comply with the prescribed treatment plan may be challenging because children develop the disease at an age when they are usually very active. The child, who may have little pain, often finds immobilization difficult.

PROMOTE NORMAL GROWTH AND DEVELOPMENT

Give parents suggestions to help redirect the child's energy within the limitations in mobility imposed by treatment. A return to school promotes a feeling of normality. Coordinate the return to school by facilitating the child's use of an elevator or ramp as needed in that setting. Partner with the family to provide instruction for school personnel and other children to foster understanding of the child's condition and treatment. Activities that involve peers also help the child achieve developmental milestones. Help the child adjust to wearing a brace.

Growth and Development

Legg-Calvé-Perthes disease primarily affects boys with an average age of 7 years. These school-age children are industrious and independent. Suggest activities that redirect energy and promote normal development. These may include horseback riding, which promotes hip abduction; swimming to increase mobility; handcrafts to promote fine motor skills; and computer activities to stimulate cognitive development.

COMMUNITY-BASED NURSING CARE

Both the child and the family should be aware that treatment generally takes more than 2 years. Emphasize the importance of following the treatment plan to ensure adequate hip containment and proper healing. Teach the family how to care for a child in traction and how to check the child's skin for breakdown (see Table 29–11 later in this chapter). Follow-up visits should be arranged at regular intervals in addition to home care visits during the period of traction.

Evaluation

Expected outcomes of nursing care are elimination of hip pain and discomfort, normal development during the period of immobilization, absence of complications, and parent and child knowledge of the treatment regimen.

Slipped Capital Femoral Epiphysis

Slipped capital femoral epiphysis (SCFE) occurs when the femoral head is displaced from the femoral neck. This condition is seen in 10 of 100,000 adolescents, commonly in the prepubertal

growth spurt, between the ages of 12 to 15 years in boys and 10 to 13 years in girls. Boys are more often affected than girls. Black children and those with predisposing factors are affected more often than other children (Georgiadis & Zaltz, 2014).

ETIOLOGY AND PATHOPHYSIOLOGY

The cause of SCFE is unknown. Predisposing factors include obesity, a recent growth spurt, and endocrine disorders such as hypothyroidism and hypogonadism.

Slippage of the femoral head occurs at the proximal epiphyseal plate, and the femur displaces from the epiphysis (see *Pathophysiology Illustrated: Slipped Epiphysis*). Slippage is usually gradual (chronic), but may also result from acute trauma. The synovial membrane becomes inflamed, edematous, and painful. If untreated, callous formation occurs, resulting in a deformed hip with limited range of motion.

Growth and Development

Obesity is a known risk factor for SCFE. Increasing rates of obesity among children contribute to an increasing risk for the disorder. Research continues to demonstrate a relationship between body mass index (BMI) and SCFE. High rates of elevated BMI likely play a role in both bilateral SCFE occurrences and increasing incidence of the condition (Compton, 2014; Witbreuk et al., 2013). Nurses are well positioned to work with children and families to teach weight reduction strategies and to share information about the numerous health risks associated with elevated BMI.

CLINICAL MANIFESTATIONS

Symptoms include a limp knee; thigh, groin, or hip pain; and loss of hip motion. Out-toeing, decreased internal rotation, and external rotation with flexion of the leg are symptomatic (Georgiadis & Zaltz, 2014). The condition is categorized as *acute* (sudden onset with less than 3 weeks' duration), *chronic* (longer than 3 weeks' duration), or *acute-on-chronic* (an additional slippage in a child with a chronic condition), depending on the onset and severity of symptoms. The child with an acute slip has sudden, severe pain and cannot bear weight. An acute slip may be associated with traumatic injury. The youth may be able to walk (stable) or unable to bear weight (unstable).

CLINICAL THERAPY

A complete history provides information about risk factors and the development of the condition. Radiographs confirm the diagnosis. A bone scan, ultrasound, CT, and MRI may also be performed.

The goal of medical management is to stabilize the femoral head while keeping displacement to a minimum and retaining as much hip function as possible. Surgical treatment is usually necessary; this involves fixation of the epiphysis with screws or pins. If the condition is stable, a single screw into the hip in an outpatient procedure is sufficient for stabilization; if unstable, surgical treatment may include traction and surgery.

Prognosis is related to the severity of the deformity and the occurrence of complications, such as avascular necrosis of the femoral head or **chondrolysis** (the breaking down and absorption of cartilage).

Nursing Management

For the Child With Slipped Capital Femoral Epiphysis

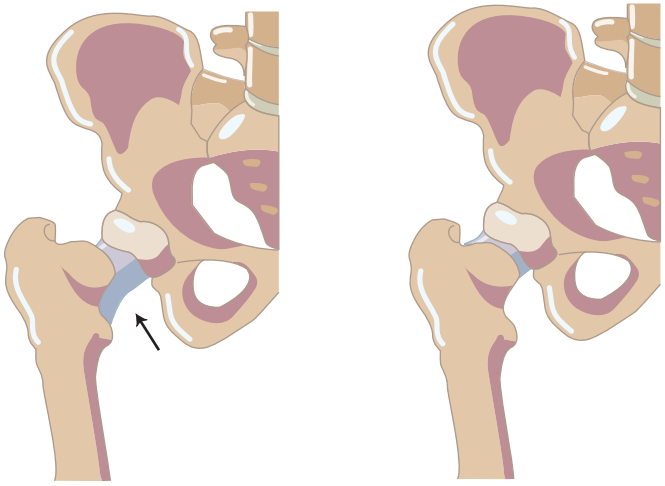
Nursing Assessment and Diagnosis

The child usually presents with hip pain or referred pain to the groin, thigh, or knee and limited mobility. A thorough history is needed to assess for injury as a cause. Assess the child's range of motion, pain, and limp, if apparent. Refer the child for treatment immediately if SCFE is suspected. This condition is considered to be an emergency, and it is essential that the child be treated immediately to keep weight off the affected joint (Georgiadis & Zaltz, 2014).

Among the nursing diagnoses that may apply to the child with SCFE are the following (NANDA-I © 2014):

- ***Mobility: Physical, Impaired,*** related to treatment
- ***Pain, Acute,*** related to hip injury
- ***Body Image, Disturbed,*** related to treatment
- ***Development: Delayed, Risk for,*** related to mobility restrictions
- ***Obesity*** related to immobility

Pathophysiology Illustrated: **Slipped Epiphysis**



Slipped epiphysis | Normal hip

In slipped capital femoral epiphysis, the femoral head is displaced from the femoral neck at the proximal epiphyseal plate.

- ***Tissue Perfusion: Peripheral, Ineffective,*** related to traction, casting, and other treatments
- ***Knowledge, Readiness for Enhanced (Child and Parent),*** related to disease process and treatment

Planning and Implementation

Nursing management involves caring for the child in traction or after surgery, administering medications and other pain-control interventions, maintaining mobility within the limits imposed by treatment, providing adequate nutrition, educating the child and family about the disorder, providing emotional support, and promoting compliance with the treatment plan.

ENCOURAGE APPROPRIATE NUTRITIONAL INTAKE AND PHYSICAL ACTIVITY

A growing adolescent needs increased amounts of proteins, carbohydrates, and calcium to promote skeletal healing. Provide written instructions about nutritional requirements to promote bone healing and maintain an ideal body weight. If a child is overweight, encourage weight loss by decreasing the percentage of fat and sugar in the diet and by increasing physical activity that is safe to do. Weight loss decreases pressure on the femoral epiphysis and can also lead to a more positive self-image. Incorporate upper body exercises into treatment, both to assist in weight control and to build muscle. A few visits to physical therapy may facilitate a program of upper body exercise and teach safe ways of increasing the total amount of physical activity.

PROVIDE EMOTIONAL SUPPORT

Because the onset of SCFE is usually unexpected, the child and family may find themselves facing surgery with little warning. Explain the treatment plan simply and thoroughly. Reassure the child and family that with proper compliance, treatment should be successful.

DISCHARGE PLANNING AND HOME CARE TEACHING

Help the family plan for the child's return to school. If attendance is not possible for a time because of traction or surgery, arrange for tutors and computer communication with school as needed. Follow-up visits are necessary until the child's epiphyseal plates close. It is not uncommon for SCFE to occur in the other hip. Make sure the child and family are aware of symptoms such as decreased range of motion or pain that could indicate onset of the disorder in the other hip. Tell parents to contact their healthcare provider immediately if these symptoms occur.

Evaluation

Expected outcomes of nursing care for the child with slipped capital femoral epiphysis include maintenance of normal weight and recommended nutritional intake, absence of complications of immobility, successful adaptation to school following treatment, and family recognition of the need for ongoing monitoring for complications.

Disorders of the Spine

Scoliosis

Scoliosis is a lateral S- or C-shaped curvature of the spine that is often associated with a rotational deformity of the spine and ribs. Many people exhibit some degree of spinal curvature; curvatures of more than 10 degrees are considered abnormal. Curves are either idiopathic or compensatory, the latter occurring as the spine curves to compensate for a structural deformity such as leg length discrepancy. Idiopathic scoliosis occurs most often in girls, especially during the growth spurt between the ages of 10 and 13 years. From 1% to 3% of adolescents manifest with idiopathic scoliosis of greater than 10 degrees. A smaller number of children manifest infantile scoliosis before 3 years of age or juvenile scoliosis from 3 to 10 years (Lombardi, Akoume, Colombini, et al., 2011).

ETIOLOGY AND PATHOPHYSIOLOGY

The cause of scoliosis is complex. Structural scoliosis may be congenital, idiopathic, or acquired (associated with neuromuscular disorders such as muscular dystrophy or myelodysplasia, or secondary to spinal cord injuries).

In idiopathic structural scoliosis (the most common type), the spine for unknown reasons begins to curve laterally, with vertebral rotation. The most common curve is a right thoracic and left lumbar deformity. As the curve progresses, structural changes occur. The ribs on the concave side (inside of the curve) are forced closer together, while the ribs on the convex side separate widely, causing narrowing of the thoracic cage and formation of the rib hump. The lateral curvature affects the vertebral structure. Disc spaces are narrowed on the concave side and spread wider on the convex side, resulting in an asymmetric vertebral canal (Figure 29–10).

Scoliosis can also occur in congenital diseases involving the spinal structure and in the musculoskeletal changes seen in conditions such as myelomeningocele, cerebral palsy (see Chapter 27), or muscular dystrophy. Disturbances in platelet function, melatonin levels, and bone-related trace substances are sometimes evident (Lombardi et al., 2011). Scoliosis can also be acquired after injury to the spinal cord.

CLINICAL MANIFESTATIONS

The classic signs of scoliosis include truncal asymmetry, uneven shoulder and hip height, a one-sided rib hump, and a prominent scapula. The child does not usually complain of pain or discomfort.

Figure 29–10 **Clues for early detection of scoliosis. A child may have varying degrees of scoliosis. For mild forms, treatment will focus on strengthening and stretching. Moderate forms will require bracing. Severe forms may necessitate surgery and fusion. Clothes that fit at an angle, such as this teenage girl's shorts, and anatomic asymmetry of the back provide clues for early detection.**

CLINICAL THERAPY

Generally, observation and radiographic examination are used to diagnose scoliosis. Additional diagnostic studies include MRI, CT, and bone scanning, which are used occasionally to assess the degree of curvature. The goal of medical management is to limit or stop progression of the curvature.

Early detection is essential to successful treatment. Adequate treatment and follow-up maximize the child's chances for proper spinal alignment. The treatment regimen chosen depends on the degree and progression of the curvature and the reaction of the child and family to medical management.

Treatment of children with mild scoliosis (curvatures of 10 to 20 degrees) consists of exercises to improve posture and muscle tone and to maintain, or possibly increase, flexibility of the spine. Emphasis is placed on building strength toward the outside of the curve while stretching the inside of the curve. However, these exercises are not a cure, and the child should be evaluated by a physician at 3-month intervals, with radiographic evaluation every 6 months.

Medical management of moderate scoliosis (curvatures of 20 to 40 degrees) includes bracing with a Boston brace. The goal of wearing a brace is to maintain the existing spinal curvature with no increase. Brace wear begins immediately after diagnosis. To achieve maximum effectiveness, the brace should be worn 23 hours per day. Brace treatment is lengthy, favorite sports may not be allowed, it can affect body image, and it requires a high degree of compliance, all of which can be difficult for adolescents.

Children with severe scoliosis (curvatures of 40 to 50 degrees or more) generally require surgery, which involves spinal fusion. The majority of spinal fusions are performed using segmental instrumentation of the spinal cord with hooks, wires, rods, and screws (Lubicky, Hanson, Riley, et al., 2011; Scottish Rite Hospital, 2011). Examples of surgical approaches include Luque wires, Cotrel-Dubousset (CD) instrumentation, Texas Scottish Rite Hospital system, and Moss-Miami system. These treatments stabilize the spine well during surgery, may be accompanied by bone grafting to the spine, and require no long-term therapy or postoperative casting; instrumentation remains permanently in the back. Following surgery with wires or instrumentation, the child is on bed rest during a recovery period and then is generally fitted with anteroposterior plastic shells (also called thoracolumbar sacral orthotics) that are worn for several months to provide stability for the spine.

Nursing Management

For the Child With Scoliosis

Nursing Assessment and Diagnosis

School nurses often screen children for scoliosis, generally in the fifth and seventh grades. Several states mandate this screening, but it is not universal in all states, nor is it now recommended for all children (U.S. Preventive Services Task Force, 2014). When abnormalities are noted, refer the child to an orthopedic center for further evaluation. Children should be examined every 6 to 9 months thereafter. If scoliosis is detected, the child's brothers and sisters should be examined and observed closely. Scoliosis screening involves visual observations of the following:

From the front:

- Is the head midline?
- Are the shoulders at the same height?
- Is there the same amount of space between the arms and body on each side?

From the back:

- Is the head midline?
- Are the shoulders at the same height?
- Are the scapulae equally prominent and at the same height?
- Is the spine straight?
- Is there the same amount of space between the arms and body on each side?
- Are the hips at the same height?

With the adolescent holding hands together and bent over slightly:

- Are the scapula humps even?

With the adolescent holding hands together and bent over toward the floor:

- Are the flank humps even?
- Is the spine straight?
- Is there a marked roundness when viewed from the side? (evidence of kyphosis)

Once scoliosis has been identified, the focus becomes education and follow-up. Any child with scoliosis should have a comprehensive neurologic, cardiac, and respiratory examination, since the rib cage deformity can influence the functioning of these systems.

Professionalism in Practice **Scoliosis Screening of Adolescents**

The U.S. Preventive Services Task Force previously recommended screening of all young adolescents for scoliosis, generally in the school and/or office setting. However, analysis of research studies has not shown that screening of all adolescents aids in the identification or treatment of this condition, and it may be costly and difficult in the school setting and lead to unnecessary health referrals. Therefore, the 2014 guidelines did not recommend screening of all adolescents for scoliosis (U.S. Preventive Services Task Force, 2014). School nurses can work with administration in their districts to make decisions about whether or not scoliosis screening should be done on children in the school setting. The decision and information about scoliosis should be communicated with families.

The following nursing diagnoses may apply to the child with scoliosis (NANDA-I © 2014):

- ***Health Behavior, Risk-Prone,*** related to duration and intensity of exercise prescription
- ***Mobility: Physical, Impaired,*** related to brace or movement restrictions and pain following surgery
- ***Skin Integrity, Risk for Impaired,*** related to brace
- ***Knowledge, Deficient,*** related to unfamiliarity with disease process and home care
- ***Body Image, Disturbed,*** related to deformity and brace wear

Common nursing diagnoses for the child having surgery can be found in the accompanying *Nursing Care Plan*.

Nursing Care Plan: The Child Undergoing Surgery for Scoliosis

1. Nursing Diagnosis: *Knowledge, Deficient (Child and Parents),* related to lack of information about surgery (NANDA-I © 2014)

GOAL: The child and parents will verbalize understanding of the disease, its treatment, and the surgical procedure.

INTERVENTION	RATIONALE
• Teach the child and family about the course of the disease, its signs and symptoms, and treatment. Provide appropriate handouts. Encourage the child and parents to ask questions.	• Understanding and involvement increase motivation and compliance while reducing fear.
• Begin preoperative teaching at the time of admission. Orient the child to hospital and postoperative procedures. Before surgery, have the child demonstrate log-rolling, range-of-motion (ROM) exercises, and the use of an incentive spirometer. Discuss pain management.	• Preoperative teaching and familiarity with hospital procedures reduce the stress related to surgery and postoperative complications.

EXPECTED OUTCOME: Child and family will accurately verbalize knowledge about the disease and its treatment. Child and family will ask appropriate questions about postoperative care.

2. Nursing Diagnosis: *Breathing Pattern, Ineffective,* related to hypoventilation syndrome (NANDA-I © 2014)

GOAL: The child will show no signs of respiratory compromise.

INTERVENTION	RATIONALE
• Monitor respiratory status, especially after the administration of analgesics. Apply pulse oximeter.	• Evaluation of the child's respiratory condition anticipates and avoids complications. Analgesics such as morphine may increase or potentiate respiratory compromise.
• Administer oxygen if ordered.	• Oxygen increases peripheral oxygen saturation to 95%–100%.
• Have the child use an incentive spirometer.	• Spirometry increases lung expansion and aeration of the alveoli.
• Monitor intake and output.	• Adequate hydration promotes loose secretions and helps prevent infection.
• Reposition the child at least every 2 hr.	• Repositioning ensures inflation of the lung fields.

EXPECTED OUTCOME: Child will have normal respiratory patterns.

3. Nursing Diagnosis: *Injury, Risk for,* related to neurovascular deficit secondary to instrumentation (NANDA-I © 2014)

GOAL: The child's neurovascular system will remain intact as evidenced by circulation, sensation, and motor assessments. The child will feel no numbness or tingling.

INTERVENTION	RATIONALE
• Monitor the child's color, circulation, capillary refill, warmth, sensation, and motion in all extremities. Perform neurovascular assessments every 2 hr for the first 24 hr and then every 4 hr for the next 48 hr. Record presence of pedal and distal tibial pulses every hour for 48 hr. Report changes and abnormal findings immediately.	• When the spinal column is manipulated during surgery, altered neurovascular status, thrombosis formation, and paralysis are possible complications. Postoperative risks include loss of bowel or bladder control, weakness or paralysis, and impaired vision or sensation.
• Have the child wear antiembolism stockings until ambulatory. The stockings may be removed for 1 hr 2–3 times daily.	• Antiembolism stockings prevent blood clots and promote venous return. Thrombus formation is a postoperative risk.
• Check for any pain, swelling, or a positive Homans sign (pain in the calf of the leg when the toes are dorsiflexed). Record any evidence of edema.	• Swelling may indicate a tight dressing and tissue damage. A positive Homans sign and pain may indicate thrombus formation.
• Monitor input and output.	• Abnormalities may indicate a fluid shift problem.
• Log roll while on bed rest. Encourage and assist the child with ROM exercises, both passive and active as prescribed.	• Log rolling maintains a straight spine. Exercises promote mobility and reduce risk of thrombus formation.

(*continued*)

Nursing Care Plan: The Child Undergoing Surgery for Scoliosis (*continued*)

EXPECTED OUTCOME: Child will exhibit only temporary alteration (pale skin, faint pulse, and edema occur but they resolve within the initial postoperative phase). Child will return to the preoperative baseline state by discharge.

4. Nursing Diagnosis: *Pain, Acute,* related to spinal fusion with instrumentation (NANDA-I © 2014)

GOAL: The child will verbalize an adequate level of comfort or show absence of pain behavior within 1 hour of a specific nursing intervention.

INTERVENTION	RATIONALE
• Assess the level of pain and initiate pain management strategies as soon as possible. Use patient-controlled analgesia if ordered.	• Adequate pain management allows for faster healing and a more cooperative patient. Patient-controlled analgesics may be effective.
• Administer pain medication around-the-clock to help ensure pain relief, especially during the first 48 hours. Monitor epidural blocks and patient-controlled analgesia or other methods used for pain control.	• Medicating around-the-clock helps to maintain comfort. Monitoring ensures patient safety.
• Use nonpharmacologic pain management techniques, such as imagery, relaxation, touch, music, application of heat and cold, and reduced environmental stimulation to supplement medications (see Chapter 15).	• Alternative treatments also interrupt the pain stimulus and provide relief. Nonpharmacologic methods can be an effective adjunct to pain management.
• Document pain assessment interventions and the child's response.	• Proper documentation guides the selection of the most effective means of pain control.
• Reassure the child that some discomfort is expected and that a variety of measures can be tried to reduce discomfort.	• Realistic expectations decrease anxiety and give the child a sense of control.

EXPECTED OUTCOME: Child will experience pain relief early in the postoperative period.

Planning and Implementation

An important aspect of nursing care is client education. Client adherence to prescribed measures is critical to the success of treatment. Children and their families need to understand the condition and the stages of treatment; this is particularly true for adolescents undergoing treatment for scoliosis.

Children or adolescents facing surgery require education, reassurance, and support. Teach about pain control and the patient-controlled analgesia (PCA) pump. Often children donate some of their own blood prior to surgery, and the family may also donate so blood transfused in surgery is the children's or a family member's. Teach the child the safety that this ensures. The adolescent will benefit from learning about deep breathing, positioning, surgical incision, and all other aspects of postoperative care. The *Nursing Care Plan* summarizes nursing care for the child undergoing surgery for scoliosis.

PROMOTE ACCEPTANCE OF THE TREATMENT PLAN

Provide instructions about exercises that will help decrease the severity of the spinal curvature, and obtain baseline exercise levels. Demonstrate the exercises, and explain their purpose (i.e., to strengthen back muscles). Help the child adjust to wearing a brace. Adolescents, in particular, may be reluctant to wear an external device such as a brace. To promote a sense of control, allow the adolescent to choose when to exercise and when to be out of the brace, within the treatment guidelines. Provide reassurance and encouragement and promote interaction with peers. Suggest that the adolescent work with a peer support person who is being treated for scoliosis or has had the condition in the past. Provide information about fashionable clothing that can be worn with the brace and facilitate visits to department stores that will help the teen shop for clothing.

DISCHARGE PLANNING AND HOME CARE TEACHING

Identify and address home care needs well in advance of discharge after spinal surgery. The child will need to adapt to a new set of body mechanics. Show the child how to do simple tasks without bending or twisting the torso. Have the child demonstrate the ability to perform activities of daily living before discharge from the hospital. Partner with physical therapy/rehabilitation personnel to plan for the youth's needs related to safe and effective movement with the brace.

Activities for the child who has had spinal surgery are commonly limited for a period of time. The child can usually walk and perform physical activity such as gentle swimming, but lifting heavy loads, bending or twisting at the waist, or engaging in activities such as skiing, rollerblading, bicycle riding, and many other sports may not be allowed. Restrictions usually should be followed for 6 to 8 months, depending on the type of surgery and the surgeon. Emphasize to both the child and the family the importance of compliance. Give written discharge instructions to the child and family. Follow-up visits are important. The child should be examined 4 to 6 weeks after discharge, then every 3 to 4 months for 1 year, and every 1 to 2 years thereafter. The metal hardware in the back will set off metal detectors at airports. The teen should be prepared to tell screeners about the implants so that alternative screening methods can be used.

Several organizations provide information and assistance to families of children with scoliosis. Make referrals as appropriate.

Evaluation

Expected outcomes of nursing care for the child with scoliosis treated by brace are maintenance of intact skin and compliance with prescribed therapy. Expected outcomes after surgical correction are given in the accompanying *Nursing Care Plan*.

Clinical Reasoning **Adolescent Braces for Scoliosis**

It is common knowledge that adolescents are concerned about body image and that wearing a brace can be challenging. Although there has been controversy about the efficacy of braces for scoliosis treatment, studies have found that bracing significantly decreases the progression of high-risk curves to the need for surgery (Brox, Lange, Gunderson, et al., 2012; Weinstein, Dolan, Wright, et al., 2013). Healthcare providers may need to address psychosocial coping issues in order to ensure compliance with brace therapy for scoliosis. What assessments can assist you in learning about the activity level, social interactions, and well-being of adolescents beginning scoliosis treatment?

Torticollis, Kyphosis, and Lordosis

Torticollis is tilt of the head caused by rotation of the cervical spine. The cause is generally an injury sustained to the sternocleidomastoid muscle at the time of birth or to a cervical spine abnormality. Stretching exercises or surgical lengthening of the sternocleidomastoid muscle are usual treatments. Occasionally, the cause of torticollis is visual impairment, leading to constant turning in one direction to see with the better eye.

Kyphosis (hunchback) and lordosis (swayback) are two other types of spinal curvature that may occur in children. Clinical therapy depends on the cause and degree of the curvature, and the age of the child at onset. Nurses can perform thorough musculoskeletal assessments of children (see Chapter 5) and refer any children with abnormalities for further evaluation. (See Table 29–4.)

Growth and Development

Postural lordosis is a characteristic finding in toddlers but should disappear by the school-age years.

Additional Disorders of the Bones and Joints

Osteoporosis and Osteopenia

Osteoporosis, a condition in which there is decreased density and mass of bone, promotes the risk of fractures and is commonly associated with aging. However, children can have osteoporosis (also known as *metabolic bone disease* or a bone mineral density more than 2.5 standard deviations below the norm) related to imbalanced nutrition or other pathologic conditions. Osteoporosis is preceded by osteopenia or low bone mass, which is between 1.0 and 2.5 standard deviations below the norm (Szadek & Scharer, 2014).

ETIOLOGY AND PATHOPHYSIOLOGY

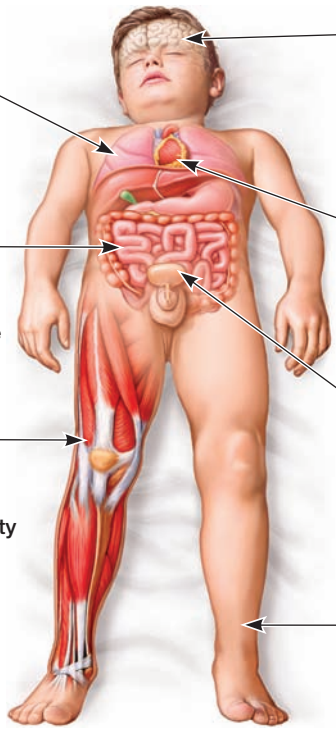
Very-low–birth-weight infants who are premature often have osteopenia of prematurity because much of the bone mass is usually acquired in the latter weeks of pregnancy. In addition, they may have other health problems after birth and be unable to ingest enough nutrients to meet metabolic needs for bone growth. Premature infants are often less active than others, which decreases the amount of mechanical loading on their bones, a factor known to increase bone resorption and decrease bone mass (Rack et al., 2011).

A group of children who may show signs of osteoporosis are those who have decreased mechanical loading. Children with spina bifida or cerebral palsy, conditions that interfere with ambulation, have limited pressure on bones and resultant lowered bone mass in affected extremities and spine. Some

TABLE 29–4 Clinical Manifestations of Kyphosis and Lordosis

CONDITION	CLINICAL MANIFESTATIONS	DIAGNOSTIC TESTS AND CLINICAL THERAPY	NURSING MANAGEMENT
KYPHOSIS			
Excessive convex curvature of the cervical thoracic spine	Visible hunchback or rounded shoulders; shortness of breath or fatigue; abdominal creases and tight hamstrings in severe cases	*Diagnostic tests:* Spinal curvature is assessed by having the child bend 90 degrees at the waist and looking at the scapular area from the side. Diagnosis is confirmed by radiograph. *Clinical therapy:* Exercises are prescribed for mild condition; bracing is commonly used; surgery is performed in severe cases.	Provide support. Encourage exercises and diligent brace wear. Help the child to deal with the psychologic stress of altered body image.
LORDOSIS			
Excessive concave curvature of the lumbar spine with an angle of more than 60 degrees; most common in prepubescent girls and African Americans	Presence of swayback; prominent buttocks; hip flexion contractures; tight hamstrings	*Diagnostic tests:* Spinal curvature is assessed by looking at the standing child from the side. Lumbar lordosis is confirmed by visualizing the spine on standing, lateral radiograph. *Clinical therapy:* Treatment focuses on exercises and postural awareness. Bracing and surgery are rarely prescribed.	Provide support. Reassure the child and family that the condition is often outgrown as the child matures. Encourage physical conditioning exercises and follow-up examinations on a yearly basis.

Pathophysiology Illustrated: **Effects of Immobility**



Respiratory System
- Decreased lung expansion and impaired gas exchange
- Retained secretions, ineffective cough, and increased risk of infection

Cognitive and Nervous System
- Sensory deprivation
- Confusion, anxiety, stress
- Delayed development
- Disturbed sleep patterns
- Disturbed self-concept and body image

Nutrition and Gastrointestinal System
- Decreased intestinal tone and motility leading to constipation
- Decreased metabolic rate
- Anorexia, nausea, negative nitrogen balance

Cardiovascular System
- Increased cardiac workload
- Orthostatic hypotension
- Pooling of blood and thrombus formation

Musculoskeletal System
- Decreased muscle strength and tone
- Lack of coordination, altered gait, and increased risk of falls
- Decreased range of motion and joint flexibility
- Pain and activity intolerance
- Osteopenia and osteoporosis

Urinary System
- Decreased bladder tone and stasis of urine
- Increased risk of urinary tract infection and renal calculi

Integumentary System
- Pressure ulcers
- Pain
- Infection

For older children at risk of developing osteoporosis, calcium and vitamin D intake is encouraged and oral supplements may be given. Standing therapy for those who are nonambulatory can provide mechanical weight and enhance bone density. Bisphosphonates, calcitonin, fluoride, and parathyroid hormone may be used to treat children and adolescents with osteoporosis (Szadek & Scharer, 2014). When a cast or other immobilizing device is removed from a child, a program of gradually increasing exercise in collaboration with physical rehabilitation professionals promotes bone strengthening and lowered risk for fractures or related sequelae.

other conditions are associated with lower bone mass, including Turner syndrome, growth hormone deficiency, osteogenesis imperfecta, juvenile rheumatoid arthritis, and diabetes. Children who are treated for disorders or injuries with casting and bracing are also at high risk of osteoporosis due to immobilization.

Finally, adolescence is a period when adequate intakes of calcium and vitamin D are needed to maximize bone formation and prevent osteoporosis later in life. Adolescents, particularly females, often do not meet the recommended daily allowance (RDA) for these nutrients and are at risk for osteoporosis even though it may not be manifested for years. Other lifestyle patterns of youth that decrease bone formation are smoking, alcohol use, excessive soda intake, and keeping weight at a very low level. Those with anorexia nervosa are at risk for osteoporosis and increased risk of fractures (Mehler, Cleary, & Guadiani, 2011).

CLINICAL MANIFESTATIONS

Osteoporosis is a silent disease, as is its precursor osteopenia; those who have the disorders are often without signs or symptoms for years. It may become apparent when a baby or child has a fracture and radiologic studies make the problem evident.

CLINICAL THERAPY

Bone mineral content and density are measured by single-photon absorptiometry (SPA), dual-photon absorptiometry (DPA), and dual-energy x-ray absorptiometry (DEXA); ultrasound may be used to assess preterm infants (Rack et al., 2011). Serum studies such as thyroid, bone-specific alkaline phosphatase, phosphorus, and type I collagen studies can be used to measure osteoblastic and osteoclastic activity. Vitamin D and calcium are measured, but since over 90% of the body's calcium is stored in bone, serum calcium is not accurately reflective of bone density.

Premature newborns at risk of osteopenia of prematurity need collaborative management by neonatologists, neonatal nutritionists, and neonatal nurses. Breast milk is enhanced by adding special fortifiers; premature formula should be used rather than regular baby formula. When infants need enteral or parenteral feedings, calcium-to-phosphorus ratios are carefully balanced to enhance osteoblastic activity. There is evidence to suggest that assisted range-of-motion exercise can promote weight gain and bone mineralization in premature infants (Schulzke, Kaempfen, Trachsel, et al., 2014).

Nursing Management

For the Child With Osteoporosis or Osteopenia

Nursing Assessment and Diagnosis

Nurses identify newborns, children, and adolescents at risk of developing low bone mass and density. This is accomplished by identifying diseases and medications putting the child at risk, as well as history of fractures or malabsorption disorder. Ask about exercise and activity patterns, and physical therapy for children

who are nonambulatory. Dietary intake is measured periodically for all youth at health promotion visits, and RDAs for calcium, phosphorus, and vitamin D are compared to intake.

Nursing diagnoses that may apply to the child with osteoporosis include the following (NANDA-I © 2014):

- ***Nutrition, Imbalanced: Less than Body Requirements,*** related to inability to consume essential nutrients
- ***Injury, Risk for,*** to bones related to decreased bone mass and density
- ***Health Maintenance, Ineffective,*** related to inadequate dietary intake

Planning and Implementation

Perform a dietary analysis of children at risk. (See Chapter 14 for detailed methods for diet assessment.) Refer children at risk to nutritionists and a physician for further education and diagnosis. Suggest referrals to physical rehabilitation to recommend weight-bearing exercise. Administer nutritional supplements when prescribed, and teach families how to give these medications. Partner with families to provide therapy that stimulates weight bearing for nonambulatory children. Teach parents how to recognize fractures in children who may not have normal sensation and are unable to report them. Edema, unusual shape of a limb, fussiness of the child, and falls should be reported promptly.

When osteoporosis is caused by immobility, many other symptoms occur as well. Be alert for these problems and integrate physical activity into care as much as possible to minimize their effects.

Evaluation

Expected outcomes of nursing care for the child with a potential for osteoporosis include adequate intake of recommended amounts of nutrients, absence of fractures, and normal findings on studies of bone mineral content and density.

Osteomyelitis

Osteomyelitis is an infection of the bone, most often one of the long bones of the lower extremity. It may be acute or chronic and may spread into surrounding tissues. Although osteomyelitis may occur at any age, it is most common in children between the ages of 1 and 12 years. Boys are affected 2 to 3 times as often as girls, primarily because they have a greater incidence of trauma. Overall incidence is 5 in 10,000 youth (Thomsen & Creech, 2011).

ETIOLOGY AND PATHOPHYSIOLOGY

Osteomyelitis is caused by a microorganism, usually bacterial but possibly viral or fungal. *Staphylococcus aureus* is the most common causative pathogen; others include *Escherichia coli*, *Neisseria meningitidis, Streptococcus pneumoniae*, *Mycobacterium tuberculosis, Borrelia burgdorferi,* and *Kingella kingae* (Bautista, Gholve, & Dormans, 2011; Thomsen & Creech, 2011). Common sources of infection are upper respiratory infection, trauma to the bone, and surgery.

The infecting organism spreads through the bloodstream or through a penetrating injury to the bone, where it becomes established. Infections in children often begin in the metaphysis (see Figure 29–1), which has a sluggish blood supply (Bautista et al., 2011). Eventually the infection may penetrate the bone cortex and periosteum. Inflammation and abscess formation can interrupt the blood supply to the underlying bone, affect the surrounding soft tissue, and, if the infection is left untreated, lead to necrosis.

CLINICAL MANIFESTATIONS

Symptoms include pain and tenderness with swelling, decreased mobility of the infected joint, and fever. Redness over the area may occur. The child may refuse to walk or may limp. The onset of acute osteomyelitis is generally rapid and is therefore sometimes misdiagnosed as a sports injury.

CLINICAL THERAPY

A history suggestive of osteomyelitis includes an upper respiratory infection or blunt trauma followed by pain at the area of a growth plate. Laboratory evaluation shows leukocytosis and an elevated erythrocyte sedimentation rate (ESR) and C-reactive protein. Radiographs and bone scans may identify the area of involvement. A needle aspiration of the site or a blood culture can confirm the diagnosis and provide a culture of the causative organism. Other studies may include enzyme-linked immunosorbent assay (ELISA) for Lyme antibody titer, antistreptolysin-O for recent streptococcal infections, or purified protein derivative (PPD) for exposure to tuberculosis (Thomsen & Creech, 2011).

Medical management begins with the intravenous administration of a broad-spectrum antibiotic, even before culture results are available. Since *S. aureus* is a common cause of infection, the antibiotic should be effective against this organism. Treatment is influenced by the possibility of methicillin-resistant *S. aureus* (MRSA), so intravenous antibiotics are usually vancomycin or clindamycin, drugs effective against MRSA (see Chapter 16). After the culture results are obtained, the antibiotic may be altered. Oral antibiotics are given once an adequate response has occurred. However, extended intravenous home therapy may be used. Antibiotic therapy continues for about 3 to 6 weeks. The cause of infection is not always identified from culture, so ESR and C-protein levels are followed carefully in these cases to identify if treatment is successful. When an adequate response is not obtained within 2 to 3 days, the area may be aspirated again or surgically drained. Intravenous fluids may be administered to ensure adequate hydration. In children with extensive orthopedic surgery or in those with immunosuppression, a short course of prophylactic antibiotic may be administered after surgery.

Growth and Development

Osteomyelitis in a newborn is of great concern because before 18 months of age the blood vessels cross the growth plates. This creates a higher risk of epiphyseal involvement with resultant limb length discrepancy. Poor feeding, crying when moved, and refusal to move a limb may indicate osteomyelitis.

Prompt diagnosis and treatment usually completely resolve the infection. The prognosis is related to the initiation of therapy—the earlier treatment begins, the better the outcome. Long-term unfavorable outcomes include disruption of the growth plate, which can interrupt growth, and damage to the joints from septic arthritis.

Nursing Management

For the Child With Osteomyelitis

Nursing Assessment and Diagnosis

A thorough history, including information about the onset of symptoms and a history of recent infections or puncture wounds, is essential. Ask about immunization status, especially tetanus vaccine. Assess the affected area for signs of redness, swelling, pain, and decreased range of motion. Measure vital signs; increased

temperature and pulse in particular may provide clues about worsening infection. When osteomyelitis is possible, all cultures of blood or wound must be taken before antibiotic therapy is started.

Among the nursing diagnoses that may apply to the child with osteomyelitis are the following (NANDA-I © 2014):

- ***Pain, Acute,*** related to biologic injury
- ***Mobility: Physical, Impaired,*** related to discomfort
- ***Infection, Risk for (Sepsis),*** related to spread of infection
- ***Imbalanced Nutrition: Less than Body Requirements,*** related to loss of appetite
- ***Knowledge, Readiness for Enhanced (Child and Parent),*** related to lack of information about disease process

Planning and Implementation

Nursing management focuses on administering antibiotics, protecting the child from spread of the infection, and encouraging a well-balanced diet. Use standard precautions, with transmission-based precautions for any drainage from the site of infection.

OBTAIN CULTURES AND BLOOD WORK

Blood cultures and cultures of any open wound must be performed before the first dose of antibiotic when osteomyelitis is suspected. Obtain continuing blood samples as needed to monitor ESR and C-reactive protein levels. See the *Clinical Skills Manual* SKILLS.

ADMINISTER FLUIDS AND MEDICATIONS

Administer intravenous fluids as ordered to maintain the child's hydration status. Antibiotics are administered intravenously, at first, then orally. Monitor the intravenous site and provide care for the central line, if one is used. See the *Clinical Skills Manual* SKILLS.

In the early stages of the infection, analgesics are prescribed to relieve the associated pain and joint tenderness.

PROTECT FROM THE SPREAD OF INFECTION

Strict aseptic technique and transmission-based precautions should be used during all dressing changes. Children and family members should avoid direct contact with any dressings or drainage. Teach good hygiene practices, including hand hygiene, to maintain infection control. Take vital signs and evaluate the child frequently for symptoms indicating the spread of infection (e.g., increasing pain, difficulty breathing, increased pulse rate, fever).

ENCOURAGE A WELL-BALANCED DIET

Educate both the child and the parents about healthy dietary choices that promote healing. A high-protein diet and extra vitamin C will contribute to this process. Encourage increased fluid intake to provide adequate hydration and circulation.

DISCHARGE PLANNING AND HOME CARE TEACHING

Emphasize the importance of completing the full course of antibiotic therapy, especially for children who have had an abscess or lesion surgically drained. Some children may be discharged on intravenous antibiotics if the family is willing to learn the procedure for medication administration and care of the central line. Several sessions of demonstration and return demonstration are needed to ensure safe administration. If the family is unable to perform antibiotic therapy, a home infusion company may be available to come to the home and administer the medication. Explain that failure to follow the prescribed antibiotic therapy may result in chronic infection. Emphasize the importance of returning for blood analysis to monitor progression of healing.

Consider the child's age and developmental level and partner with the family to plan quiet activities and access to schoolwork. Provide suggestions for the family if the child will be immobilized at home.

Clinical Tip

If the child needs to remain home for a period of time during treatment for osteomyelitis, help the family plan for completion of school tasks. The nurse can partner with other health disciplines that are available to plan for the following:

- Contact the school and ask that work be sent home.
- Arrange for a tutor if needed.
- Facilitate computer communication between child, teacher, and other students.
- Help the family plan for help at home to monitor the child when the family needs to be at work or performing other tasks.
- Refer families to financial resources as appropriate for the services the child needs.
- Suggest activities that the child can do at home that foster developmental progress.

Evaluation

Expected outcomes of nursing care for the child with osteomyelitis include the following:

- The child has no signs of infection or sepsis.
- The child completes the prescribed course of antibiotics.
- Intake of fluids and nutrients is adequate for good health.
- The child's pain is effectively managed.
- The child is able to return to normal activities of daily living.

Skeletal Tuberculosis and Septic Arthritis

Skeletal tuberculosis (Figure 29–11) and septic arthritis are two infections that, although infrequent, may affect children and adolescents. See Table 29–5 for diagnostic tests and medical and nursing management for these infections.

Figure 29–11 **This boy from Kenya had surgery to correct severe kyphosis and scoliosis caused by tuberculosis of the spine. A Risser cast has been applied to maintain stability of the spine and thoracic cage during healing. Notice the area cut out of the cast to allow for auscultation of the abdomen, as well as to facilitate the child's comfort and adequate intake of food.**

TABLE 29–5 Clinical Manifestations of Skeletal Tuberculosis and Septic Arthritis

CONDITION	CLINICAL MANIFESTATIONS	DIAGNOSTIC TESTS AND CLINICAL THERAPY	NURSING MANAGEMENT
SKELETAL TUBERCULOSIS			
Rare microbacterial infection that can be very destructive. The spine is the most frequent site of infection (Pott disease), with joints and other sites sometimes affected.	Depending on the site, pain, limp, severe muscle spasms, kyphosis, muscle atrophy, "doughy" swelling of joints, decreased joint motion, changes in reflexes, low-grade fever	*Diagnostic tests:* Diagnostic studies include tuberculosis skin test, complete blood count, synovial fluid analysis, and radiographs of affected limb or joint. *Clinical therapy:* Antibiotic therapy (using a combination of drugs) for 6–9 months is the treatment of choice. The affected site is immobilized. Disease may become resistant to these drugs, and additional drug therapy may be necessary.	Educate the child and family about the disorder and stress the importance of complying with long-term antibiotic therapy. Test all members of the family for tuberculosis. Report the disease to the local health department. Facilitate the immobilization and physical therapy of the child at home.
SEPTIC ARTHRITIS			
Joint infection of the synovial space most often caused by *Haemophilus influenzae*, *Staphylococcus*, and *Streptococcus*. The most common site of infection is the knee, followed by the hip, ankle, and elbow.	Fever, pain and local inflammation, joint tenderness, swelling, loss of spontaneous movement	*Diagnostic tests:* CBC with differential, ESR, blood cultures. Diagnosis is made based on joint aspiration findings. Results are commonly 100,000 WBCs and 75% neutrophils, ESR greater than 44 mm/hr. Radiographic changes may not be evident until later in the disease process. *Clinical therapy:* This is a medical emergency requiring prompt treatment to avoid permanent disability. Treatment involves joint aspiration, open drainage, and irrigation, followed by intravenous antibiotic therapy for 3–4 weeks and then oral antibiotics. If the full course of antibiotic treatment is not completed, the child risks recurrent infection and further degeneration of the infected joint.	Educate the child and family about the disorder and emphasize the importance of proper antibiotic therapy. Carefully position the painful joint. Administer antibiotics as prescribed. Use transmission-based precautions. Encourage fluids to ensure adequate hydration. Support and rest the joint; provide activities that do not require joint movement.

Achondroplasia

Dwarfism is a genetic condition usually resulting in an adult height of 58 inches or less. The most common cause of dwarfism is achondroplasia, which causes short arms and legs. The torso and head are approximately normal size, but decreased growth of long bones causes short stature. This is known as *disproportionate short stature*. Achondroplasia is caused by an abnormal gene of chromosome 4 and occurs in 1 in 15,000 to 40,000 births (March of Dimes, 2012). The gene is coded to produce proteins called *fibroblast growth factor receptors*. When fewer receptors are produced, the cells cannot respond normally to signals from growth factors. Achondroplasia may occur as a new genetic mutation with no previous family history or can occur when one or both parents are also dwarfs. There are other less common forms of dwarfism with about 200 identified types. (Refer to Chapter 3 for further information about genetic disease transmission.)

Children with achondroplasia have short legs and arms, short fingers with a separation between middle and ring fingers, and a large, prominent forehead. Hydrocephalus sometimes occurs in children with achondroplasia. (See Chapter 27 for a description of hydrocephalus.) Most children with the disorder inherit the gene from one parent. Since only one faulty gene must be present for manifestation of the disorder, it is a dominant characteristic. When a child inherits two copies of the gene from two affected parents, a fatal form of achondroplasia occurs, which is characterized by a small thorax, respiratory failure, and death in infancy.

Children with the disorder are diagnosed prenatally, at birth, or shortly after. When there is a family history, genetic testing before or after birth identifies the presence of the fibroplast growth factor receptor 3 (*FGFR3*) gene on chromosome 4. Characteristics common in the growth disorder include frequent otitis media, dental malocclusion, short fingers, bowing of legs, marked lordosis, and sleep apnea. The child may be slow at meeting gross motor developmental milestones (Ireland et al., 2012).

There is no treatment for the disorder at this time. Gene therapy and growth plate targeting are being explored as possible future treatments (Laederich & Horton, 2012). Some children and adults with dwarfism have undergone limb-lengthening procedures such as that described later in this chapter. Other orthopedic intervention may be needed to treat back pain or bone problems. For those children who develop hydrocephalus, insertion of a shunt to divert excess fluid may be needed. Treatment of conditions such as otitis media and malocclusion of teeth is provided.

Nursing Management

Nurses play an important role in helping families when a child is diagnosed with achondroplasia. If a parent is a dwarf or there is a positive family history of dwarfism, genetic counseling should be offered prenatally. Explain findings of testing and provide assistance with decision making about pregnancy if needed. Nurses assist parents who have a child with achondroplasia to adjust to the diagnosis, particularly if the parents have had no previous experience with the condition. They may feel guilt and anxiety; contact with other families who have children with achondroplasia can be a supportive intervention.

Nurses help the child with achondroplasia to develop a positive self-concept during childhood. Many resources, such as the organizations listed in the next paragraph, provide suggestions about how to foster a positive self-concept, adjust the home to facilitate the dwarf, and assist the child with adjustments in school settings. Partner with school nurses or counselors to ensure the child's successful inclusion in all school facilities and an individualized education plan. While some families decide to explore limb-lengthening procedures, most organizations state that focus should be placed on development of a healthy self-image rather than encouraging limb lengthening.

Nurses provide careful assessments of children throughout childhood. Head circumference is especially important in early childhood to identify hydrocephalus if it should occur. Carefully evaluate growth with specialized growth grids for achondroplasia, evaluate dental health at each visit, and perform developmental assessment with special emphasis on gross motor skills. Suggest activities such as swimming and biking that provide activity with little stress on bones. Assist the family by providing resources that assist with planning for car safety seats, methods of adjusting the home, and partnering with the school to provide a supportive atmosphere for the child. Some helpful organizations include Little People of America, Dwarf Athletic Association of America, Human Growth Foundation, Magic Foundation for Children's Growth and Related Adult Disorders, and March of Dimes. Refer for care for otitis media and provide postoperative care if tympanostomy tubes are inserted (see Chapter 19). Refer to dentists and orthodontists and encourage regular dental care.

Marfan Syndrome

Marfan syndrome is another example of a condition inherited in an autosomal dominant manner. About 1 in 5000 to 10,000 children are affected with the syndrome, which manifests with several conditions of connective tissue (Kumar & Agarwal, 2014; Rosenbush & Parker, 2014). The most common problems are cardiac (mitral valve prolapse, aortic regurgitation, abnormal aortic root dimensions), skeletal (pectus excavatum, long arms and digits, scoliosis, elongated head, high arched palate), ocular (lens subluxation), and respiratory (pneumothorax). The woman with Marfan syndrome has an increased risk of complications during pregnancy, primarily related to the extra requirements placed on the heart. The average age for diagnosis is 3 years, with a heart murmur as the usual finding. Careful assessment identifies additional characteristics of the condition along with a positive family history.

Diagnosis is made after a complete family history, a detailed physical examination, an eye examination, a thorough heart examination, radiographs of the chest, and MRI or CT.

There is no treatment for the syndrome, which causes abnormal formation of fibrillin matrix in connective tissue. However, early diagnosis can be successful in treating the cardiac abnormalities with medication or surgery to prevent dissection of the aorta, the major cause of death. Diagnosis in children is often difficult because many features of Marfan syndrome are not apparent until adolescence. Surgery may be needed to correct scoliosis, pectus excavatum, or pneumothorax. Careful monitoring throughout life is needed to prevent and treat abnormalities associated with the disorder.

Nursing Management

Nursing management of Marfan syndrome begins with identification of infants and children with symptoms of the disorder. Once diagnosed, collaboration with a cardiologist, ophthalmologist, and orthopedist is needed throughout the child's life. The child may require surgery for one or more conditions, can require antibiotics during elective procedures or dental care if the mitral valve is affected, and needs echocardiogram and other cardiac studies regularly. The nurse may need to explain the disorder to the family and provide referrals for genetic counseling. Case management for the numerous medical specialists will be advantageous. The child needs support during childhood to learn about the disorder and to manage the medication and monitoring required.

Clinical Reasoning **Autosomal Dominant Disorders**

Both achondroplasia and Marfan syndrome are autosomal dominant disorders. Does this mean that the child needs one or two genes to manifest the disorders? If one parent has the disorder, what is the chance that a pregnancy will result in an affected child? Will there ever be a carrier who does not manifest the disease? See Chapter 3 for further information about autosomal dominant inheritance.

Osteogenesis Imperfecta

Osteogenesis imperfecta (OI), also known as *brittle bone disease*, is a connective tissue disorder that primarily affects the bones. Children with this condition have fragile bones that are more likely to fracture. Osteogenesis imperfecta occurs in 1 in 10,000 to 15,000 live births and affects boys and girls equally (van Dijk et al., 2011).

The underlying disorder is a biochemical defect in the production of collagen. The disease is genetically transmitted, generally in an autosomal dominant inheritance pattern, although some types are transmitted in a recessive pattern. The most common types are caused by mutations on the *COL1A 1* or *COL1A 2* genes on chromosomes 17 and 7, respectively (van Dijk et al., 2011).

Clinical manifestations include multiple and frequent fractures; blue sclerae; thin, soft skin; altered joint flexibility; short stature; enlargement of the anterior fontanelle; weak muscles; soft, pliable, brittle bones; and short stature. Conductive hearing loss can occur by adolescence or young adulthood.

Osteogenesis imperfecta is classified into four main types. In type I disease, the most common form, children have fragile bones, blue sclerae, weakened tooth dentin, and possible hearing loss that manifests in adolescence. In type II disease, the ribs and skeleton are extensively involved; most children with this form of the disease die in utero or shortly after birth. Type III disease is identified in the newborn period or in infancy when the child sustains numerous fractures and manifests blue sclerae.

Severe bone fragility and kyphoscoliosis are observed. Type IV disease is characterized by fractures without other symptoms of the disease. Bowing of the legs and other structural deformities can occur; however, the incidence of fractures decreases beginning in puberty. Recent genetic research has identified up to 11 different genetic mutations leading to various types of OI (Ben Amor, Rauch, Monti, et al., 2013; Womack, 2014).

Improved knowledge about the genetic transmission of this disease means that some cases of OI can be identified before birth using ultrasound or collagen analysis of chorionic villus cells or genetic testing. In many cases, however, diagnosis of OI is made only when the child has a delay in walking or sustains a fracture. Radiographic evaluation may detect old as well as new fractures. This may lead to an erroneous diagnosis of child abuse. Tests such as DEXA can be used to measure bone density. Serum alkaline phosphatase may be elevated; other measures of bone metabolism such as serum osteocalcin, procollagen 1 C-terminal peptide, collagen 1 teleopeptide, and urine deoxypyridinoline studies may be performed occasionally to measure effects of medication.

There is no cure for OI. Medical management consists primarily of fracture care and prevention of deformities. The goal is to maximize the child's independence and mobility while minimizing the risk of fractures. Treatment includes physical therapy; casting, bracing, or splinting; surgical stabilization; nutritional management with high vitamin D and calcium; and bisphosphonate medication such as pamidronate. Health supervision that includes dental examinations and hearing screening is important. Hematologic stem cell transplant has been used successfully in some children with severe OI and is under further research.

Nursing Management

Nursing care is primarily supportive and focuses on educating the parents and child about the disease and its treatment. The family may have been suspected of child abuse before the disease was diagnosed; explain the similar presenting symptoms of these cases. Ask about favorite activities of the child since these will need to be integrated into plans for physical activity and developmental progression. Perform careful growth measurements and developmental screening; ensure health promotion visits include dental and hearing screening.

To prevent fractures, children with osteogenesis imperfecta must be handled gently. Support the trunk and extremities using a blanket whenever moving the child. Tasks such as bathing and diapering may cause fractures and should be performed carefully. Never pull the legs upward during diaper changes, but slip a hand gently under the hips to raise them.

Children commonly have several fractures during childhood. The period of immobility and casting causes further bone breakdown due to decreased weight bearing, further increasing the chance of fracture. Children should have a well-balanced diet with additional vitamin C, vitamin D, and calcium to encourage healing and bone growth. Calories should be limited to maintain weight at recommended levels since immobility can lead to overweight and these children are generally short for their age. Partner with parents if the child is receiving experimental bisphosphonate medication so that doses are properly administered and serum/urine samples are obtained for monitoring.

When the child needs a fracture stabilized in surgery, or is having rods inserted to strengthen bones, surgical care management is important. Assess the child's vital signs and growth measurements. Obtain accurate weight before surgery and again after with the cast in place. Administer fluids and use pain-control techniques such as medication and other comfort measures. Be alert for signs of infection such as osteomyelitis, or respiratory or urinary tract infection. Begin fluids and perform dietary teaching before discharge to promote intake that fosters healing. Follow activity orders precisely to minimize safety hazards for the child. Partner with physical and occupational therapists to plan for the child's return to home and school, and to ensure the family can perform ROM exercises and other therapies. Ensure that the family has an approved car safety seat to transport the child.

Emphasize the importance of maintaining normal patterns of growth and development. Help toddlers explore and interact safely in their environment. Socialization is essential during the school-age and adolescent years. Encourage exercise, such as swimming, to improve muscle tone and prevent obesity. Adaptive equipment and motorized wheelchairs promote independent functioning. Maintenance of function can depend on proper rehabilitation services. Arrange and manage such services for the family.

The Osteogenesis Imperfecta Foundation provides information about the disease and can put families in touch with others who have the disease. Parents should receive genetic counseling. For parents who have a child with type II or III osteogenesis imperfecta, the terminal nature of the condition necessitates psychologic support, links to potential resources, and assistance with managing other tasks of family life. (See Chapter 13 for management of end-of-life care.) The siblings and extended family will need support to understand the disease and deal with their feelings and the affected child.

Expected outcomes include minimal fractures with optimal healing, normal range of motion, maintenance of a healthy diet and recommended weight, achievement of developmental milestones, family support, and adequate resources to provide necessary treatments for the child.

Muscular Dystrophies

The muscular dystrophies are a group of inherited diseases characterized by muscle fiber degeneration and muscle wasting. These disorders can begin early or late in life, and onset can be at birth or gradual. They are all terminal disorders, but the progression can vary from a few to many years.

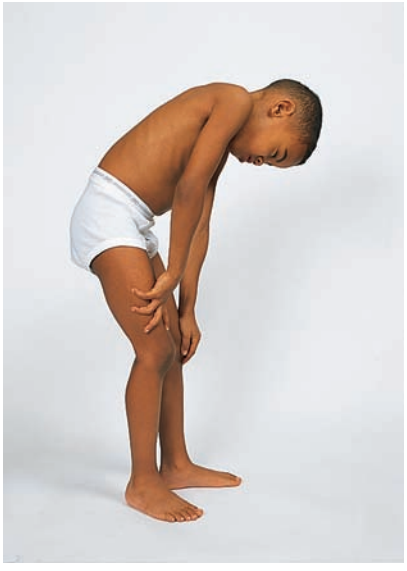
Many types of muscular dystrophies affect children and adults. The most common form of childhood muscular dystrophy is Duchenne muscular dystrophy (pseudohypertrophic), which occurs in 1 per 3500 live male births (Theadom et al., 2014). **Pseudohypertrophy** refers to enlargement of the muscles as a result of their infiltration with fatty tissue. The gene for Duchenne muscular dystrophy was identified in 1987; it is carried in the Xp21.2 region of the chromosome and is either absent or deleted in affected children. This area codes for a protein called *dystrophin*, which is needed as a muscle membrane stabilizer. In the absence of dystrophin, a cascade of cellular events occurs, leading to necrosis in the fibers and their replacement by connective tissue. Since this is an X-linked disorder, it is seen only in males. There is similar incidence in various ethnic groups.

Becker muscular dystrophy is also X-linked and affects 1 in 30,000 boys (Becker Muscular Dystrophy, n.d.). Although the gene mutation is similar to Duchenne, it is milder in form. Other rare muscular dystrophies manifest in infancy, later childhood, or adolescence. There are a variety of genetic mutations ranging from X linked to autosomal.

A

B

C



D

E

Figure 29–12 **Gowers maneuver. Since the leg muscles of children with muscular dystrophy are weak, these children must perform the Gowers maneuver to raise themselves to a standing position. *A* and *B*, The child first maneuvers to a position supported by arms and legs. *C*, The child next pushes off the floor and rests one hand on the knee. *D* and *E*, The child then pushes himself upright.**

Children with muscular dystrophy have generalized muscle weakness. They compensate for weak lower extremities by using the upper extremity muscles to raise themselves to a standing position (Gowers maneuver) (Figure 29–12). (See Table 29–6.)

Diagnosis and classification are most often based on clinical signs and the pattern of muscle involvement. Biochemical examinations such as serum enzyme assay, muscle biopsy, and electromyography confirm the diagnosis. Serum creatine kinase (CK) is elevated early in the disease. Muscle biopsy can measure dystrophin, the muscle protein that is deficient in muscular dystrophy. Genetic testing establishes the specific abnormality and type of disease present. Testing of newborns may be offered to families who have one child with the disease since this helps some families to adapt and prepare for the care the child will need. Respiratory function is measured periodically with pulmonary function tests and overnight pulse oximetry.

There is no effective treatment for childhood muscular dystrophy. Research is being directed at several techniques to repair mutations by gene therapy, override the genetic error in order to produce dystrophin, and apply stem cell therapy (Goyenvaile, Seto, Davies, et al., 2011). The steroids prednisone and deflazacort may preserve muscle function, preserving walking for a longer period. Rehabilitative therapy is needed to maximize independence and physical activity and to decrease hazards of immobility. Children and families can benefit from mental health support to help them in adapting to the progressive and terminal nature of the disease. A common complementary care used for muscular dystrophy is dietary enhancement. This enhancement includes giving vitamins A, C, E, D, and B-complex; minerals such as calcium, magnesium, zinc, and selenium; probiotic supplement; omega-3 fatty acids; herbal remedies such as green and rhodiola rosea teas; muscular and immunologic enzymes such as coenzyme Q10, N-acetyl cysteine, acetyl-L-carnitine, creatine, L-theanine; and melatonin to promote sleep. Massage is often used to assist with reduction of muscle spasms (University of Maryland Medical Center, 2011).

Progressive weakness and muscle deformity result in chronic disability (Figure 29–13). Respiratory infections are vigorously treated with deep breathing, coughing, nebulizer treatments, and antibiotics. Comprehensive and regular cardiac evaluations are recommended. The team approach to managing the child with muscular dystrophy ensures a comprehensive management plan. Team members should include physicians (pediatrician, orthopedic surgeon, neurologist), nurses, physical and occupational therapists, a nutritionist, psychologist or mental health therapist, and a social worker.

TABLE 29–6 Clinical Manifestations of Muscular Dystrophies of Childhood

TYPE OF DYSTROPHY	CLINICAL MANIFESTATIONS	CLINICAL THERAPY
DUCHENNE MUSCULAR DYSTROPHY		
X-linked recessive disorder seen in boys (on *Xp21* gene); however, 30%–50% of affected children have no family history *Onset:* within the first 3–4 years of life	Delayed walking; frequent falls; easily tired when walking, running, or climbing stairs; toe walking, hypertrophied calves; waddling gait; lordosis; positive Gowers maneuver; intellectual disability frequently seen	Supportive care; physical therapy and braces to help maintain mobility and prevent contractures Most children are wheelchair bound by 12 years of age; death usually occurs during adolescence from respiratory or cardiac failure
BECKER MUSCULAR DYSTROPHY		
X-linked recessive disorder *Onset:* usually after 5 years	Symptoms are similar to those of Duchenne muscular dystrophy, but milder and delayed; child is mobile until late teens; normal intelligence; congestive heart failure; contractures	Supportive care, same as for Duchenne muscular dystrophy Slow progression; death usually occurs from the third to the fifth decade of life
FACIOSCAPULOHUMERAL MUSCULAR DYSTROPHY		
Autosomal dominant disorder (on 4q35 chromosome) *Onset:* later childhood and adolescence	Face, shoulder girdle, lower limbs affected; unable to raise arms over head; lordosis; cannot close eyes, whistle, smile, or drink from a straw because of inability to move face; characteristic appearance includes facial weakness, winging of the scapula, thin arms, well-developed forearms	Physical therapy Slow progression; confined to wheelchair as older adult, but usually attains normal life span
EMERY-DREIFUSS MUSCULAR DYSTROPHY		
X-linked recessive disorder (on *Xq28* gene) *Onset:* childhood	Early onset of contractures followed by weakness; Achilles tendon, elbow, and spine affected; muscle weakness in upper body follows, with lower body weakness occurring later; cardiac conduction defect may occur	Physical therapy Surgery Pacemaker insertion
CONGENITAL MUSCULAR DYSTROPHIES		
Autosomal recessive group of disorders *Onset:* present at birth	Muscle weaknesses present at birth; motor development delay; contractures and joint deformities; hypotonia	Correction of skeletal deformity (orthosis or surgery) Usually nonprogressive

Figure 29–13 This young boy with muscular dystrophy needs to receive tube feedings and home nursing care. He attends school when possible and is able to use an adapted computer.

Nursing Management

Nursing care focuses on promoting independence and mobility and providing psychosocial support that helps the child and family deal with this progressive, incapacitating disease. Nearly all body systems become involved in the disease, and emotional care is important as well for child and family.

Monitor cardiac and respiratory functioning frequently. Assess urinary function and frequency of bowel movements. Periodically measure strength and range of motion. Assess mobility via ambulation or assisted device. Perform periodic developmental and nutritional assessments. Meet with teachers to evaluate the child's learning needs and functional level in the classroom. Evaluate the family's risk and protective factors for managing this chronic and fatal disorder.

Administer oxygen or respiratory therapy as ordered. Encourage the child to be independent for as long as possible. Concentrate on what the child can accomplish, and do not ask the child to complete tasks that may prove frustrating. Encourage parents to establish an individualized education plan with the school system. Reading books to the child, listening to tapes, and watching television offer the child stimulation during hospitalization. Exercise as tolerated contributes to muscle strength. Physical therapy helps the child ambulate and prevents joint contractures. It is important to provide back support and recommended posture by keeping the child's body in alignment when confined to a wheelchair. Provide information about complementary care that the family chooses to use.

Health Promotion The Child With Muscular Dystrophy

The child with muscular dystrophy needs close monitoring and intervention to foster growth and development in spite of a chronic and terminal disease. The nurse in health promotion can assist the child and family in many ways.

Growth and Development Surveillance

- Perform developmental screening of the young child.
- Refer to early intervention programs that establish educational plans to foster development.
- Provide resources and ideas for the parents based on the child's status rather than expected age norms. Plan interventions to maximize the highest level of function possible.
- Measure growth at each healthcare visit and plot on growth grids. Be alert for the child who is gaining weight related to decreased activity.
- Ensure visits with specialists in respiratory medicine and cardiology as recommended.

Nutrition

- Perform 24-hour analysis and evaluate for all essential nutrients. Base the analysis on the child's height and weight rather than chronologic age.
- Ask about appetite and food likes and dislikes.
- Encourage adequate fluid, whole grains, fruits, and vegetables to maintain bowel function.
- For the infant with muscular dystrophy, evaluate intake carefully; gavage feeding or nutritional supplementation such as with high-calorie formula may be needed.

Physical Activity

- Carefully monitor physical ability at each visit. Observe for decreases in movement, difficulty ambulating, or a history of falls.
- Partner with physical therapists to ensure range of motion and proper positioning of extremities.
- Explore activities that the child can do as mobility decreases. Swimming and upper body exercise may be good options.
- If the child is using a wheelchair, evaluate fit, safety, and ability to move the chair by arm controls.
- Physical activity should be regular and daily. Ensure that the family has resources to accomplish this need.

Activities of Daily Living

- Partner with occupational therapy to evaluate the child's ability to feed, bathe, dress, and provide own oral care. Provide adaptive devices as needed.
- Encourage the family to provide time for the child to perform own self-care as much as possible.
- Make a home visit or discuss with the family adaptations that could make it easier for the child to be independent in activities of daily living. Low drawers for clothing or open shelves that do not require pulling out to get items are examples of important adaptations.

Mental and Spiritual Health

- Inquire about the child's general mood.
- Ask the parents what is best and worst about their lives at this time. Use the information to establish a list of their meaningful activities and to identify the areas most in need of support.
- Ask about sources of support such as a group for parents of a child with muscular dystrophy, family participation in faith-based activity, and extended family or neighbors.

Christina Kennedy/Alamy

- Be alert for signs of depression in child or family (see Chapter 28).
- Assist the family to establish activities to increase self-esteem in the youth. The youth should be able to make choices appropriate for developmental age.
- If the child was diagnosed at a younger age, ask what the parents have now told the child about the disease. Provide support and role-playing opportunities for parents who wish to tell the child about the terminal nature of the disorder.
- Refer for services such as genetic counseling, grief counseling, or other supportive interventions.

Relationships

- Ask about siblings and their relationship with the child with muscular dystrophy.
- Inquire about the child's participation in early intervention or school programs, and community groups. Refer the family to resources that encourage the child's interactions with peers. This is particularly important for teens.
- Ask the parents if and how often they are able to spend time with other adults.

Disease Prevention Strategies

- Immunize the child at recommended times. If the child is ill and immunization is delayed, be sure to call the family back promptly to reschedule administration of vaccines so that infectious diseases can be avoided. Annual influenza vaccine is needed. If the child is treated with steroids for the disease, follow recommendations for immunization of children on steroids.
- Teach the family to avoid crowds and known infectious persons. The child may need to be out of school for a few days or weeks if there is an influenza or other disease outbreak in the school population.
- Teach the family signs of infection, especially of the respiratory tract. Have them report these symptoms promptly.
- Monitor effects of antibiotics when administered for infection.
- Encourage daily activities that encourage deep breathing. Swimming, blowing into an incentive spirometer, or playing with a pinwheel are examples.

Health Promotion **The Child With Muscular Dystrophy (*continued*)**

Injury Prevention Strategies

- Inquire about whether the family has an emergency evacuation plan for the child in case of house fire or other emergency. Assist them to develop a plan.
- If the child is using oxygen, teach about fire safety.
- When mechanical ventilation is used at home, help the family establish emergency backup systems for power outage, such as portable generators.
- Assist the family to learn proper body mechanics to safely transfer and provide care for the child.

Parents may feel guilty and hopeless; encourage them to express their feelings. Genetic counseling is recommended for the entire family, and it is especially important to identify female relatives who are carriers of one of the X-linked disorders. Siblings may feel neglected because their brother or sister is receiving so much attention. They may be concerned that they will develop the disease, and in some families, this indeed occurs. Encourage the parents to spend individual time with each child and to involve siblings in the child's care.

Refer family members to resource and support groups such as the Muscular Dystrophy Association. Provide ongoing support during hospitalizations, management of home care, and the child's changes in condition.

Injuries to the Musculoskeletal System

Musculoskeletal injuries are classified according to the mechanism, the location, and the force of the injury. Strains, sprains, dislocations, and fractures are the most common musculoskeletal injuries in children; athletic participation and injuries from car crashes are frequent causes. Distinguishing among these injuries is often difficult. See Table 29–7. See accompanying *Evidence-Based Practice* for a discussion of backpack use by children. A detailed discussion of fractures follows.

Fractures

A fracture is a break in a bone that occurs when more stress is placed on the bone than the bone can withstand. Fractures may occur at any age; they are frequent in children because their bones are less dense and more porous than those of adults (see *Pathophysiology Illustrated: Classification and Types of Fractures*).

ETIOLOGY AND PATHOPHYSIOLOGY

Fractures in children may result from direct trauma to a bone (falls, sports injuries, abuse, motor vehicle crashes) or bone diseases that result in weakening of the bone (osteogenesis imperfecta). Children with osteoporosis or osteopenia are more prone to fractures (see description of these conditions earlier in the chapter). Trauma may be caused by an acute injury, by direct and forceful impact, or by overuse such as in chronic and repetitive

TABLE 29–7 Clinical Manifestations of Strains, Sprains, and Dislocations

CONDITION	CLINICAL MANIFESTATIONS	CLINICAL THERAPY
STRAIN		
• Stretching or tearing of either a muscle or a tendon, usually from overuse (example: back strain resulting from improper or overly heavy lifting).	• Vary according to the type and severity of the strain. Pain can be acute or chronic.	• Rest and support of the injured part until the muscle or tendon heals and normal activity can occur.
SPRAIN		
• Stretching or tearing of a ligament, usually caused by falls, sports injuries, or motor vehicle crashes. For example, an anterior cruciate ligament (ACL) tear is a severe sprain requiring reconstruction.	• Edema, joint immobility, and pain.	• For the first 24–36 hr: **R**est **I**ce **C**ompression **E**levation • After the first 24–36 hr, mobility is gradually increased.
DISLOCATION		
• Complete displacement of an articular joint surface, usually associated with falls, sports injuries, or motor vehicle crashes. Although almost any joint may be dislocated, most dislocations occur in the shoulder, knee, and hip.	• Pain and tenderness, swelling and obvious deformity, and instability of the joint.	• Varies according to the site and severity of the injury, and consists of: Shoulder: open or closed reduction followed by the application of a sling Knee: closed reduction with gentle traction, then immobilization with a splint Hip (posterior): immediate closed reduction or possibly open reduction, traction, or hip spica cast Hip (anterior): immediate closed reduction, extension traction, and hip spica cast

EVIDENCE-BASED PRACTICE | Do Heavy Backpacks Cause Back Pain?

Clinical Question

Many children wear backpacks that are heavy and are carried for large parts of the day. Low back, neck, and shoulder pain are prevalent in children, and a possible connection with backpacks has been suggested (Dockrell, Simms, & Blake, 2013). What can nurses do to reduce risk of back pain related to backpacks in children?

The Evidence

Several studies have investigated the relationships between backpack use and complaints of pain. Carrying a backpack over one shoulder, having heavier backpacks, and carrying the pack lower rather than higher were associated with greater back and shoulder pressure. Postural angle and lumbar curvature are altered by heavy backpacks. Children carrying backpacks that exceeded 10% of their body weight had a 50% increased chance of back pain, and girls more commonly experienced back pain (Rodriguez-Oviedo et al., 2012). Design, fit, and weight all may play a part in discomfort related to backpacks (Amiri, Dezfooli, & Mortezaei, 2012).

Best Practice

An association between backpack use and weight and complaints of pain appears to be evident, especially among girls. Therefore, nurses should ask about backpack use at health promotion visits and advise on how to wear them. Encourage children to store backpacks in lockers when available throughout the day in order to decrease wearing time. The American Academy of Pediatrics and North American Spine Society list recommendations for backpack use:

- Have wide, padded shoulder straps and wear the pack on both shoulders, close to the body.
- Use a padded back and waist strap.
- Be sure the backpack is lightweight (no more than 10% to 15% of the youth's weight) or consider a rolling pack if it is heavy.
- Practice back strengthening exercises and learn to bend at the knees when lifting objects.

Clinical Reasoning

How will you partner with youth who are in sports after school to plan how to carry school items and sports gear safely? What exercises can you plan to help strengthen the back and thighs for carrying a pack? Which children are most at risk for back pain from heavy backpacks (consider gender and weight)?

Pathophysiology Illustrated: **Classification and Types of Fractures**

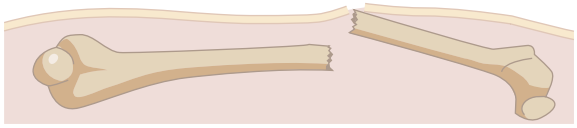
Complete (transverse) fracture

Break across entire section of a bone at a right angle to the bone shaft resulting in two or more fragments

Spiral fracture

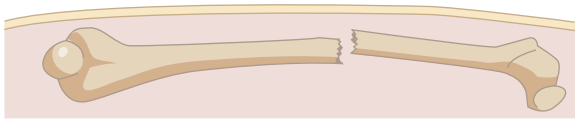
Associated with twisting force; fracture coils around the bone

Open fracture



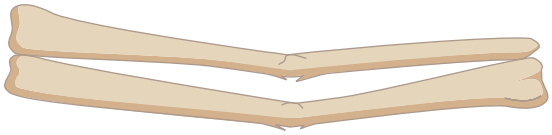
Broken bone protrudes through the skin leaving a path to the fracture site; high risk of infection exists

Closed fracture



Broken bone does not protrude through the skin

Greenstick fracture



Caused by compression force; often seen in young children

Comminuted fracture

Associated with high-impact forces; bone breaks into three or more segments

Additional types of fractures include incomplete, in which the break occurs in only one side of the cortex; oblique, in which the fracture slants across the long axis of the bone; compression, in which two bones are jammed together (usually occurs in spinal area); and compacted, in which one bone fragment is wedged into another.

activities. Child abuse is a cause of fracture and should be suspected when the type of fracture is uncommon for a given age (see Chapter 17).

CLINICAL MANIFESTATIONS

Signs and symptoms of fractures vary depending on the location, type, and nature of the causative injury. Fractures are generally characterized by pain, abnormal positioning, edema, immobility or decreased range of motion, ecchymosis, guarding, and crepitus. Childhood fractures most often involve the clavicle, tibia, ulna, and femur, with distal forearm fractures the most common type. Stress fractures are most common in the tibia, fibula, metatarsals, and calcaneus, while regular exercise can encourage bone development and be protective against fractures (Farr, Laddu, & Going, 2014; Harrington, Sochett, & Howard, 2014). Douglass, described in the chapter-opening vignette, had a fracture of his tibia. Fractures to the pelvis are often associated with motor vehicle crashes. Epiphyseal injuries are dangerous in children as they can interfere with bone growth at the site. These injuries are described using the Salter-Harris classification system (Figure 29–14).

CLINICAL THERAPY

Emergency care focuses on accurate diagnosis, pain management, and establishment of a treatment plan. Radiographs are useful for determining the exact location and type of the fracture. Medical management consists of two basic steps: (1) reduction to realign displaced or fragmented bones and (2) immobilization so that healing can take place.

A closed reduction aligns the bone by manual manipulation or traction. Sedation and additional pain management techniques will be used during closed reduction. An open reduction requires surgical alignment of the bone, often using pins, plates, wires, or screws. For open fractures, surgery must also be performed for debridement, to remove dead tissue and clean the wound. Casting is the most common external method of immobilization. Casts may be placed on extremities (short or long leg or arm cast), the upper body to immobilize the spine, or from chest to legs to stabilize pelvis or hips (spica cast). Leg casts may be walking or nonwalking casts. Cast material is either plaster or a synthetic fabric. Other external methods of stabilization include traction and splinting (later in the chapter, see Table 29–10 for types of traction). Pins may be inserted to stabilize the fracture, and can be used with or without casts or traction. A child with multiple fractures following a car crash or other trauma may need a combination of treatments.

Growth and Development

Stress fractures are becoming more common in adolescents and are most common in those who limit their intake of calories and calcium in an attempt to remain lean for sports such as distance running, cheerleading, or gymnastics (Field, Gordon, Pierce, et al., 2011). These fractures may present with chronic pain that changes in intensity. Be alert to this possibility when teenagers' diets and athletic activities place them at risk. The risk of bone fractures is increased with high cola consumption and television viewing time and with lower levels of physical activity and lower milk intake. Teach healthy diet and activity patterns to youth and their families to decrease these health risks.

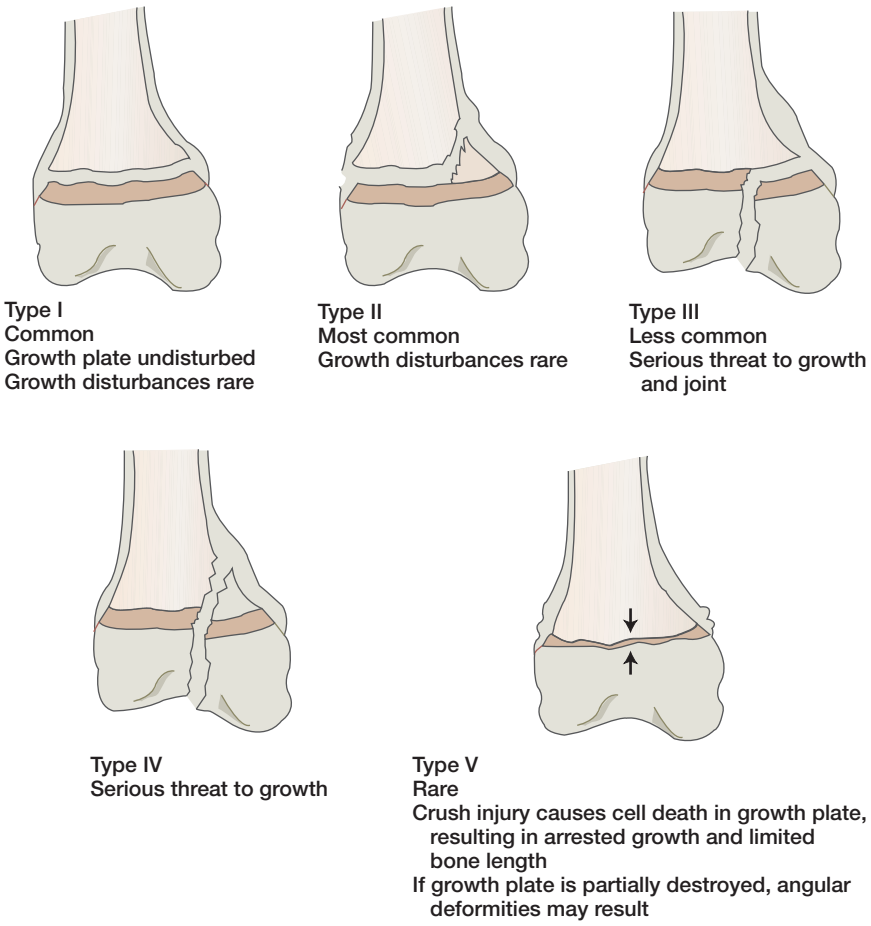


Figure 29–14 The Salter-Harris classification system is based on the angle of the fracture in relation to the epiphysis.

TABLE 29–8 Complications of Fracture Reduction

COMPLICATION	CLINICAL THERAPY
Infection Acute (may occur with open fractures) Chronic (osteomyelitis)	Debridement, drainage, culture, and treatment with antibiotics
Neurovascular injury resulting from physical nerve damage	Nerve repair
Vascular injury	Vascular repair, amputation, tendon lengthening
Malunion (undesired healed alignment of bone) or delayed union	Corrective osteotomy; prolonged immobilization
Nonunion	Surgical intervention; internal fixation
Leg length discrepancy	Shoe lift

Immobilization is essential for the bone-healing process. Healing of fractures is influenced by factors including age, size of the involved bone, and fracture site. Fractures heal more quickly in children than in adults because the periosteum or vascular outer layer of bone is thicker and remains intact even during a fracture (AAOS, 2014b). If a fracture is properly reduced, complications should be minimal (Table 29–8). Fractures involving the epiphyseal growth plate must be treated properly to minimize the chance for limb length discrepancy, joint incongruity, and angular deformities.

Nursing Management

For the Child With a Fracture

Nursing Assessment and Diagnosis

When assessing an injured child, be alert to the signs and symptoms of fractures before moving the child. When in doubt about the type of injury, apply a splint to immobilize the joints above and below the injury. Try to identify the cause of the injury by asking the child, parents, or other family members what happened. Evaluate pain, edema, and any abnormal positioning of the injured area. When a child is admitted to the emergency department or hospital, nursing assessment includes the extent of the injury, the degree of pain, and the child's vital signs (respiratory status, pulse, and blood pressure). Monitor all systems since infection, fat emboli, and other problems can emerge during the treatment period.

Several nursing diagnoses may apply to the child with a fracture. They include the following (NANDA-I © 2014):

- ***Pain, Acute,*** related to injury
- ***Skin Integrity, Risk for Impaired,*** related to treatment
- ***Infection, Risk for,*** related to open fracture or trauma
- ***Mobility: Physical, Impaired,*** related to treatment
- ***Health Behavior, Risk-Prone,*** related to peer group influence and chosen activities

Planning and Implementation

Nurses may be in community settings when children experience a fracture and may need to provide emergency care and arrange for transport. Inform emergency personnel of the assessment data to provide for safe care. In addition, be aware that repeated fractures in the same child can be a sign of other healthcare conditions. Young children may have osteogenesis imperfecta, an older child may be experimenting with risky behavior, and child abuse may have occurred if there are several fractures in various states of healing or if the parental explanation does not match the clinical presentation. Nursing care focuses on care of the child before and after fracture reduction, encouraging mobility as ordered, maintaining skin integrity, preventing infection, and teaching the parents and child how to care for the fracture. If sedation or pain blocks are used, nursing care for these procedures is needed. See the *Clinical Skills Manual* SKILLS.

When caring for a child who has undergone fracture reduction, it is important to know the signs of complications and follow protocols for assessment. Notify the physician immediately if these signs occur. The major serious complication is **compartment syndrome**, or a condition of increased pressure in a limited space such as the soft tissue of an extremity, which compromises circulation and nervous innervation (Schaffzin et al., 2013). (See Table 29–9.)

MAINTAIN PROPER ALIGNMENT

Immobilization maintains proper alignment of the fracture. Casts and traction are methods used for immobilizing an injured child. Cast care guidelines are included in Table 29–2, earlier in this chapter.

Different types of traction are used, depending on the location and type of fracture (Table 29–10). Nursing care for the child in traction is described in Table 29–11.

MONITOR NEUROVASCULAR STATUS

Neurovascular assessment is used for early detection of compartment syndrome. Compartment syndrome may occur with a crush injury or when a fracture is reduced. The swelling of inflammation reduces blood flow to the affected area, and casting

TABLE 29–9 Clinical Manifestations of Compartment Syndrome

Clinical manifestations begin about 30 min after tissue ischemia starts. Major manifestations include the following:

- Paresthesia (tingling, burning, loss of 2-point discrimination)
- Pain (unrelieved by medication, characterized by crying in the young child)
- Pressure (skin is tense, cast appears tight)
- Pallor (pale, gray or white skin tone)
- Paralysis (weakness or inability to move extremity)
- Pulselessness (weak or absent pulse)
- Poikilothermia (skin temperature assumes that of the environment)

Check extremities for:

- Color
- Temperature
- Capillary refill
- Peripheral pulses
- Edema
- Sensation
- Motor ability
- Pain

Document results and report changes or abnormal results immediately. Changes are a medical emergency.

TABLE 29–10 Types of Traction

SKIN TRACTION

Pull is applied to the skin surface, which puts traction directly on the bones and muscles. Traction is attached to the skin with adhesive materials or straps, or foam boots, belts, or halters.

DUNLOP TRACTION (CAN BE EITHER SKELETAL OR SKIN)

Used for fracture of the humerus. The flexed arm is suspended horizontally with straps placed on both the upper and lower portions for pull from both sides.

SKELETAL TRACTION

Pull is directly applied to the bone by pins, wires, tongs, or other apparatus that have been surgically placed through the distal end of the bone.

SKELETAL CERVICAL TRACTION

Used for cervical spine injuries to reduce fractures and dislocations. Crutchfield, Gardner-Wells, or Vinke tongs are placed in the skull with bur holes. Weights are attached to the apparatus with a rope and pulley system to the hyperextended head.

HALO TRACTION

Used to immobilize the head and neck after cervical injury or dislocation. Also used for positioning and immobilization after cervical injury.

A

B

C

BRYANT TRACTION (A)

Used specifically for the child under 3 years of age and weighing less than 35.0 lb (17.5 kg) who has developmental dysplasia of the hip or a fractured femur. This bilateral traction is applied to the child's legs and kept in place by wrapping the legs from foot to thigh with elastic bandages. The hips are flexed at a 90-degree angle, with knees extended. This position is maintained by attaching the traction appliance to weights and pulleys suspended above the crib. The buttocks do not rest on the mattress, but are slightly elevated off the bed.

BUCK TRACTION (B)

Used for knee immobilization; to correct contractures or deformities; or for short-term immobilization of a fracture. It keeps the leg in an extended position, without hip flexion. Traction is applied to the extremity in one direction (straight line) with a single pulley system.

D

90–90 TRACTION (D)

Used for fractures of the femur or tibia. A skeletal pin or wire is surgically placed through the distal part of the femur, while the lower part of the extremity is in a boot cast. Traction ropes and pulleys are applied at the pin site and on the boot cast to maintain the flexion of both the hip and knee at 90 degrees. This traction can also be used for treatment of an upper extremity fracture.

RUSSELL TRACTION (C)

Used for fractures of the femur and lower leg. Traction is placed on the lower leg while the knee is suspended in a padded sling. The slightly flexed hips and knees are immobilized. One force is applied by a double pulley to the foot and another force is applied upward using a sling under the knee and an overhead pulley.

E

EXTERNAL FIXATORS (E)

These devices can be used in the treatment of simple fractures, both open and closed; complex fractures with extensive soft tissue involvement; correction of bony or soft-tissue deformities; pseudoarthroses; and limb length discrepancies. They are attached to the extremity by percutaneous transfixing of pins or wires to the bone. When used to lengthen an extremity, the device can be "distracted" or turned as ordered by the surgeon for a very small amount several times daily. This separates the bone and allows new growth, gradually lengthening the extremity.

TABLE 29–11 Care of the Child With Traction or External Fixator

1. Assess the child in traction by first checking the equipment. Make sure that the equipment is in the proper position. Observe both the body appliance and the attached weights and pulleys. Make certain that the child's body is in proper alignment.
2. Assess the skin under the straps and pin insertion sites for any signs of redness, edema, or skin breakdown.
3. Assess the extremity by checking neurovascular status frequently (check warmth, color, distal pulses, capillary refill time, movement, sensation).
4. Provide pin care when ordered using sterile technique. Clean the area surrounding the pin with cotton-tipped applicators saturated with normal saline or half-strength hydrogen peroxide. Clean the area again with sterile water or more saline. Apply an antibacterial ointment, if ordered, using another cotton-tipped applicator.
5. When external skin traction is used, perform skin care every 4 hr when the traction device is removed.
6. Place a sheepskin pad under the child's extremity if prescriptions permit.

causes further constriction of blood flow. Douglass, who was described in the chapter-opening quotation, had a splint applied for several days, with casting later, to allow swelling to decrease and to minimize risk for compartment syndrome. Monitor the child's sensation to touch, temperature, movement, strength of the pulse, and capillary refill time in the extremity distal to the injury. Monitor every 15 minutes after the cast is applied for at least 2 hours and then every 1 to 2 hours, depending on the facility's policy and the child's condition. Keep the cast elevated above heart level to minimize edema. Report symptoms of compartment syndrome immediately as permanent damage to nerves and circulatory system can occur.

PROMOTE MOBILITY

The amount of mobility the child is allowed is ordered by the physician; restrictions depend on the extent and site of the fracture. Fractures of the hip or pelvis may involve body casts; wheeled carts make mobility possible. Children with leg fractures can sometimes bear weight on the cast, but if they cannot, they move around with crutches, walkers, or wheelchairs. See the *Clinical Skills Manual* SKILLS.

DISCHARGE PLANNING AND HOME CARE TEACHING

Most fractures can be easily managed at home. Activities are generally limited for approximately 8 weeks. Teach the parents and child cast care, activity restrictions, and how to identify problems that should be reported (see Table 29–2). Help parents identify any modifications that may be needed at home and school. The child who has to manage steps at home or school may need special training with crutches or a temporary ramp. Refer parents to home health nurses or home teaching services if indicated. Provide pertinent teaching to prevent future injuries. Reinforce the need for protective gear for many sports (see Chapter 17).

Evaluation

Desired outcomes for treatment of injuries is proper healing of the body parts affected, return to usual strength and range of motion, and no impairment of musculoskeletal development.

Sports Injuries

Sports injuries are the most common type of injury in youth from 13 to 19 years of age. Football, soccer, cycling, and basketball are sports commonly associated with injury, and foot–ankle injuries are most common (Atay, 2014). Fractures, described earlier, are common sports injuries of young athletes, and may be treated on an outpatient basis or may require surgery and hospitalization. Douglass, in the opening scenario, is a good example of a youth with this type of injury. However, a variety of other injuries that affect the musculoskeletal system are common in sports; strains and sprains are examples. Overuse injuries can occur when tendons, muscles, or bones are stressed excessively without adequate rest periods (Luke et al., 2011). Children and adolescents have characteristics that put them at risk for injury. These include:

- Vulnerability of growth plates to injury, especially the distal tibia and fibula
- Increased joint mobility from lax tendons and ligaments, leading to injury of the knee, ankle, and hip
- More porous bones, leading to fractures and to more common injury to underlying organs
- Lack of experience in the sport and inadequate training
- Lack of acceptance of protective gear
- Impatience with taking the time to heal after injury
- Vulnerability to spinal injury related to high-impact sports and recreation such as diving in unsupervised locations

Common sports injuries are listed in Table 29–12. Treatments for sprains, strains, dislocations, and fractures are described in the preceding sections. Head and neck injuries are discussed in Chapter 27 and dental emergencies in Chapter 19. Clear guidelines for concussion injuries have been established (Harmon et al., 2013) and are discussed in Chapter 27. General approaches to minimize and treat injuries for youth athletes follow.

Athletes can benefit from teaching that enhances performance of their sports and also minimizes chance of injury. They should receive instruction in correct techniques from a person qualified to coach and supervise children. Nurses should encourage youths to gradually increase time and intensity at a sport, rather than immediately playing a new sport for long periods of time. Parents should be encouraged to inquire about the coach's experience and also verify that the coaching staff is prepared in emergency care.

The nurse should be alert for sports injuries during contacts with children and adolescents in health promotion visits. The nurse should ask about sports participation for all youths, but especially when there are complaints of sore muscles, edema of body parts, and bruises. Neurovascular assessment of extremities,

TABLE 29–12 Common Sports Injuries

SPORT	TYPE OF INJURIES
Baseball/ basketball	• Hand and finger fractures and sprains • Contusions and sprains of upper or lower extremities; wrists, elbows, knees, and ankles are common sites • Injury to body parts when hit by a ball (e.g., broken teeth, face, head, eye, and chest injuries)
Football	• Head and neck injuries such as skull or cervical vertebrae fracture • Pulled muscles or dislocations in shoulders and legs
Gymnastics	• Wrist and elbow fractures and strains • Tendonitis in elbows and ankles/legs
Hockey (ice and inline)	• Dental injury • Leg fractures • Head and neck injuries
Soccer	• Head and neck injury • Strains and fractures of legs
Wrestling	• Fractures and dislocations of upper and lower extremities

Clinical Reasoning The Child Wearing a Cast

Douglass was admitted to the clinic today for application of a short leg cast. He fractured his tibia nearly a week ago when he was on a trampoline with three friends, trying to see who could jump the highest. Douglass slipped and his leg hit the frame on the side. His friends helped him off the trampoline and found someone to transport Douglass to the emergency department. They then reached his mother by phone, who rushed to the hospital when she heard the news.

His mother states that he is now 12 years old and in middle school. He has been going to a friend's house nearly every day after school and spending time on activities such as the trampoline and rollerblading, as well as watching television and playing video games. She felt this was safer than him being at home alone during her work hours, but is now starting to wonder about whether to allow Douglass to engage in activities with his friend.

A splint has provided support for several days and has allowed the swelling to decrease before today's cast application. Douglass has been non–weight bearing on his leg and has been using crutches. He returned to school yesterday for part of the day and found it was hard to get to all of his classes.

- What teaching should you provide to help him keep the cast intact to ensure his safety and to alert him to signs of compartment syndrome?

including color, temperature, capillary refill time, edema, pulses, sensation, and pain, should be performed. Questions should be phrased so that sports such as skateboarding or snowboarding, which might not be performed under supervision or in organized sports programs, can be identified. Youths might not consider these "sports."

Teach the importance of warming up for 10 to 15 minutes before participation and cooling down for a corresponding period at the end of activity. Encourage wearing recommended safety gear for the sport, including equipment such as a well-fitted protective helmet, face masks, eye protection, mouth guards, elbow and wrist guards, gloves, knee pads, and shin pads. Parents may need assistance to learn about the recommended equipment and resources for purchase. Frequent updates are needed as the child grows. The child should be taught not to ignore pain.

Injuries such as muscle strains should be treated promptly. They involve several steps:

- Resting the injury for 24 to 48 hours, applying ice for 20 minutes 4 times daily, compression with an elastic wrap to provide comfort and decrease edema, and elevating the affected part above heart level
- Gradually increasing motion to the part
- Adding flexibility and resistance or strengthening exercises
- Returning gradually to the sport, usually in 2 to 3 weeks after injury

The nurse should partner with the child, family, and other health professionals to plan for activity whenever an injury has occurred. Praise the family and youth for physical activity, an important part of a healthy lifestyle. Provide community resources to foster sports participation.

Amputations

Amputation—the complete absence of a body extremity—can be either congenital or acquired. Approximately two thirds of amputations in children are congenital and one third are acquired. Congenital amputations can be caused by constrictive amniotic bands, drugs, or irradiation. Acquired amputations are generally associated with trauma or the result of a disease or disorder. Children are prone to such injuries because of their small extremities and limited skeletal mass. Lawn mower injury, exercise equipment, and motor vehicle crashes are common causes. Most common traumatic amputations involve fingers or toes but hands and limbs are also at risk.

The child with an absent limb should be fitted with a prosthesis as soon as feasible and encouraged to use it several hours daily. This fosters a positive body image, independence, and self-confidence, and also ensures that motor skills develop as normally as possible (Ulger & Sener, 2011). The prosthetic device should be reevaluated as the child progresses physically and developmentally. Children with traumatic amputations may need frequent stump reconstructions because as children grow, so do their bones, and the skin tends to adhere to the bone. Bone may need to be cut and soft tissue added to keep the stump rounded. Joint fusions or stump lengthenings may also be needed to allow the effective use of a prosthesis. Several prosthetic revisions will be needed as the child grows and develops.

Nursing Management

Nursing care focuses on providing emotional support regarding altered body image, managing pain, maintaining skin integrity, and encouraging maximal independent functioning.

Recovering from the loss of a limb is one of the most difficult challenges facing children. Emphasize what children can do rather than what they cannot do. Good listening skills are important.

The child who has had surgery or a traumatic injury experiences pain. Many techniques discussed in Chapter 15 are useful interventions. After surgery, an epidural may be the treatment of choice. Oral analgesics are used during the period of adaptation to a prosthesis if the stump is tender. Children may have "phantom" limb pain in the lost extremity, although this phenomenon decreases significantly in the first year after amputation (Burgoyne et al., 2012; Wolff et al., 2011). The child usually begins wearing the prosthetic device for 1- to 2-hour intervals. Check the skin for any redness or breakdown. If redness or breakdown develops, leave the prosthesis off and allow the skin to clear before reapplying. Have the prosthesis adjusted if necessary, and increase wearing time as tolerated by the child.

Children with amputated limbs quickly learn how to accommodate to the prosthetic device. Use physical therapy programs specifically designed to help the child perform activities of daily living.

DISCHARGE PLANNING AND HOME CARE TEACHING

Answer any questions the family has about how to care for the prosthetic device and how to perform skin checks. Encourage parents to allow the child to participate in physically and emotionally challenging peer activities. Sporting activities that enable the child to participate using modified equipment are a good way to build self-confidence and motivation. For example, ski centers may offer programs that teach children with physical disabilities how to ski, or the Paralympics may be motivating for some children. Assess the need for counseling and offer referrals as appropriate.

Chapter Highlights

- Children may develop musculoskeletal conditions as a result of congenital conditions, developmental variations, or trauma.
- Talipes equinovarus (clubfoot) is a common unilateral or bilateral variation in newborns that is treated by casting, traction, and/or surgery.
- Genu varum and genu valgum are normal variations at certain times in development that may need treatment if they persist.
- The nurse may identify developmental dysplasia of the hip (DDH) during newborn assessments and must refer the child for care to a specialist.
- Mild DDH is treated by a harness, but more severe cases may require surgery for the child to walk normally.
- Legg-Calvé-Perthes is a reversible disease most commonly seen in school-age boys, and causes necrosis of the femoral head.
- Slipped capital femoral epiphysis is treated by casting, tractions, or more commonly surgery with pinning, to stabilize the epiphysis.
- Scoliosis is a lateral curvature of the spine, and nurses commonly screen adolescents to identify the disorder.
- Scoliosis may require exercises, bracing, or surgery with instrumentation and spinal fusion.
- Osteoporosis can occur in premature infants, in children with conditions that lead to immobility and decreased weight bearing, and in youth with inadequate calcium or vitamin D intake.
- Osteomyelitis most commonly follows another infection and requires prompt treatment to prevent sepsis and serious injury to the bone.
- The child with osteogenesis imperfecta (brittle bone disease) requires careful handling by the nurse and parents to prevent fractures while fostering developmental progression.
- Muscular dystrophies are inherited diseases characterized by muscle wasting and degeneration.
- Children can experience a variety of fractures due to sports, car crashes, and other injuries.
- Many sports injuries experienced by youth can be avoided with proper equipment.
- Casts, braces, and traction are common interventions for musculoskeletal disorders; nursing interventions minimize development of complications related to these treatments.

Clinical Reasoning in Action

Peter, now 7 years old, was diagnosed at 5 years old with Duchenne muscular dystrophy. His parents are well informed about the disease since they had an older son who died of the disorder at 19 years. At the present time, he walks on his toes but is able to ambulate well with leg braces. Today, Peter is visiting the specialty clinic for children with muscular dystrophies. His braces will be checked for fit and performance, physical therapy will be performed, and he will attend a group session with other school-age children. During these visits, the parents also meet in a support group with other families and receive instruction and resources to help them with Peter's health management. As a nurse in the clinic you perform a physical and mental assessment on Peter. All findings are within normal limits, although he has had some constipation and several upper respiratory infections. You learn that he has an individualized education plan (IEP) in place at school that allows

for periods of rest and physical therapy; the parents report that he is at grade level and excels at computer skills.

1. What are the main roles of the nurse working with Peter in the specialty clinic?
2. Children with muscular dystrophy often get to a standing position by mainly using arm muscles. What is the name of the maneuver?
3. What are some of the tests performed to see if a child has muscular dystrophy, and what are the expected results?
4. Who can Peter expect to meet with on the days he goes to the specialty clinic for muscular dystrophy?
5. Construct a concept map for Peter that demonstrates the multisystem involvement of his disease and how his developmental needs can be met in spite of his disability.

Chapter 30
Alterations in Endocrine Function

Stockbyte/Getty Images

I am really worried about how Anthony is going to learn to manage all these aspects of diabetes care. Learning to check his blood sugar is pretty easy compared to counting calories and figuring out how much insulin to take and when to take it. I hope we have some time to get into a routine with his diabetes management before he gets sick. We have to work hard to keep the diabetes under control.

—Mother of Anthony, 12 years old

Learning Outcomes

30.1 Identify the function of important hormones of the endocrine system.

30.2 Summarize signs and symptoms that may indicate a disorder of the endocrine system.

30.3 Identify all conditions for which short stature is a sign.

30.4 Prioritize nursing care for each type of acquired metabolic disorder.

30.5 Develop a family education plan for the child who needs lifelong cortisol replacement.

30.6 Distinguish between the nursing care of the child with type 1 and type 2 diabetes.

30.7 Plan care for the child with an inherited metabolic disorder.

Disorders of Pituitary Function

Pituitary disorders such as growth hormone deficiency, hyperpituitarism, and precocious puberty directly affect a child's growth, while diabetes insipidus and the syndrome of inappropriate antidiuretic hormone are disorders affecting fluid balance. These disorders are discussed in the following subsections.

Growth Hormone Deficiency (Hypopituitarism)

Growth hormone deficiency (GHD) is a disorder caused by decreased activity of the pituitary gland. Because most children with this disorder secrete inadequate amounts of growth hormone, the term *growth hormone deficiency* is often preferred to *hypopituitarism*. The disorder is estimated to occur in 1 of 4000 to 1 of 10,000 people (Stanley, 2012).

ETIOLOGY AND PATHOPHYSIOLOGY

The release of growth hormone from the anterior pituitary gland is controlled by the hypothalamus, which secretes releasing and inhibitory factors (somatostatin). Growth hormone (GH) (somatotropin) stimulates linear growth and bone mineral density, as well as the growth of all body tissues. Growth hormone also stimulates the synthesis of proteins in the liver, among them the somatomedins, or insulin-like growth factors (IGFs), which promote glucose utilization by the cells and cell proliferation.

Infarction of the pituitary gland (related to sickle cell disease), central nervous system disease, tumors of the pituitary gland or hypothalamus (primarily craniopharyngiomas and gliomas), other brain tumors, cranial irradiation, brain trauma, chemotherapy, and psychosocial deprivation may cause GHD by interfering with the production or release of growth hormone. Other major causes of short stature include familial short stature, hypothyroidism, Turner

Text continues on page 866

FOCUS ON:
The Endocrine System

The endocrine system controls the cellular activity that regulates growth and body metabolism through the release of hormones. Hormones are chemical messengers secreted by various glands that exert controlling effects on the cells of the body.

- Differentiation of the reproductive and central nervous systems in the fetus
- Regulation of the pace of growth and development in concert with the central nervous system throughout childhood and adolescence
- Coordination of the male and female reproductive systems, enabling sexual reproduction
- Maintenance of an optimal level of hormones for body functioning
- Maintenance of homeostasis, a healthy internal environment, in the presence of a constantly changing external environment

Anatomy and Physiology

The endocrine and nervous systems interact to regulate responses within the body and with the external environment. The hypothalamic-pituitary axis (or system) produces a number of releasing and inhibiting hormones that regulate the function of many endocrine glands, including the thyroid, adrenal, and male and female reproductive glands. The hypothalamus synthesizes many hormones, and the pituitary gland works by stimulating or inhibiting the release of these hormones. The pituitary gland also secretes certain hormones. Hormones originating from this axis regulate growth. Other endocrine glands include the parathyroid glands and the islets of Langerhans in the pancreas (Figure 30–1). All of these glands secrete hormones into the bloodstream, which carries them to target organs or tissues. Most hormones exert their influence through interaction with receptors in the target cells of specific tissues (Table 30–1).

Hormone secretion regulation occurs through a *negative feedback* mechanism that maintains an optimal internal body environment (Figure 30–2). Negative feedback occurs when an endocrine gland or secretory tissue receives a message that the target cells have received an adequate amount of hormone. In response, further secretion is inhibited. Secretion is resumed only when the secretory tissue receives another message indicating that levels of the hormone are low.

Pediatric Differences

The endocrine system is responsible for sexual differentiation during fetal development. As the embryo develops, the initial reproductive structures are the same (a pair of gonads, two pairs of ducts, and the genital tubercle). Beginning at 7 to 8 weeks of gestation, the male embryo begins secreting testosterone, which causes the gonads to differentiate into testes. The pairs of ducts develop into the vas deferens. The female embryo begins secreting estrogen, causing the gonads to differentiate into ovaries, while the ducts develop into the uterus and the fallopian tubes. The genital tubercle also differentiates and develops the male and female external genitalia.

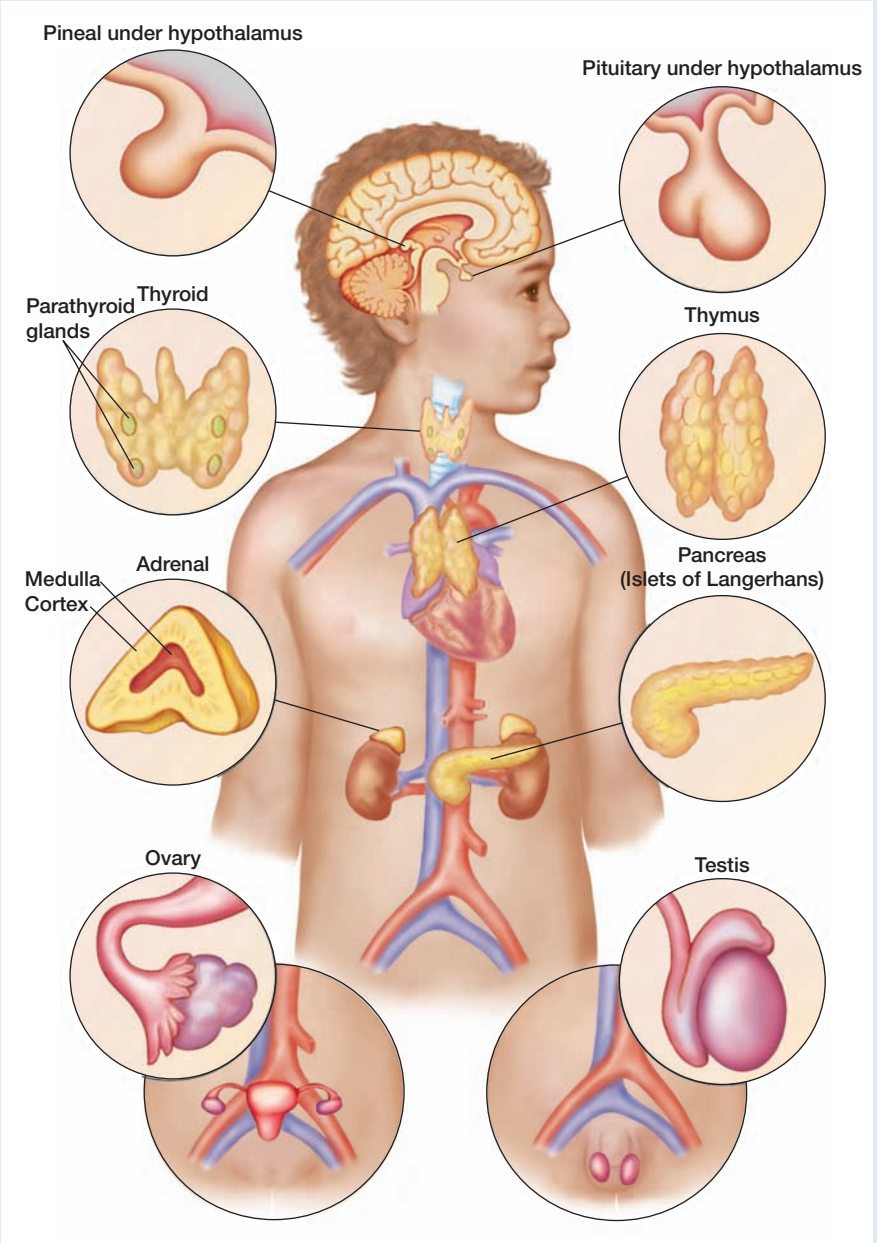

Figure 30–1 Major organs and glands of the endocrine system.

TABLE 30–1 Endocrine Glands and Their Functions

GLAND/HORMONE	FUNCTION
ANTERIOR PITUITARY	
Growth hormone (somatotropin)	Regulates metabolic process related to growth.
Thyroid-stimulating hormone (TSH)	Stimulates thyroid hormone secretion.
Adrenocorticotropic hormone (ACTH) (corticotropin)	Stimulates secretion of glucocorticoids and androgens.
Follicle-stimulating hormone (FSH) (a gonadotropin)	Stimulates secretion of estrogen; stimulates follicle maturation in ovaries. Also critical for sperm production in males.
Luteinizing hormone (LH) and interstitial cell-stimulating hormone (ICSH) (male analog) (a gonadotropin)	Stimulates secretion of androgens in males and progesterone in females.
Prolactin-releasing hormone (PRH)	Stimulates secretion of prolactin, which stimulates the secretion of milk during lactation.
Melanocyte-stimulating hormone (MSH)	Stimulates skin pigmentation.
Beta endorphins	Involved with pleasure during exercise and the alleviation of pain.
POSTERIOR PITUITARY	
Antidiuretic hormone (ADH)	Promotes water reabsorption back into blood, decreasing urine output.
Oxytocin	Stimulates uterine contractions and breast milk let-down reflex.
HYPOTHALAMUS	
Corticotropin-releasing hormone (CRH)	Regulates the release of ACTH from the pituitary gland.
Gonadotropin-releasing hormone (GnRH)	Stimulates the anterior pituitary gland to secrete luteinizing hormone (LH) and follicle-stimulating hormone (FSH).
Growth hormone-releasing hormone (GHRH)	Stimulates the anterior pituitary gland to secrete growth hormone.
Somatostatin	Inhibits the pituitary gland's secretion of growth hormone and TSH.
Thyrotropin releasing hormone (TRH)	Stimulates release of TSH and prolactin from the anterior pituitary gland.
Prolactin inhibiting hormone (PIH) (dopamine)	Inhibits prolactin, which inhibits milk production.
THYROID	
Thyroxine (T_4) and triiodothyronine (T_3)	Regulates metabolic rate of all cells, body heat production; protein, fat, and carbohydrate catabolism in all cells.
Thyrocalcitonin	Stimulates bone ossification and development.
PARATHYROID	
Parathyroid hormone	Regulates serum calcium levels and excretion of phosphorus.
ADRENAL	
Aldosterone	Increases sodium ion reabsorption, and increases potassium and hydrogen ion excretion in the kidneys.
Androgens	Stimulate bone development and secondary sexual characteristics.
Cortisol	Stimulates anti-inflammatory reactions; protects from harmful stress responses.
Epinephrine	Activates sympathetic nervous system; stimulates increase in heart rate, blood pressure, and blood glucose levels; opens airways and reduces swelling.
PANCREAS (ISLETS OF LANGERHANS)	
Insulin	Facilitates cellular glucose utilization.
Glucagon	Increases blood glucose when low by stimulating glycogenolysis.
Somatostatin	Inhibits insulin and glucagon secretion; may prevent excess insulin secretion.
OVARIES	
Estrogen	Stimulates development of breasts and ova.
Progesterone	Stimulates breast glandular development; acts to maintain pregnancy.
TESTES	
Testosterone	Stimulates production of sperm, development of secondary sexual characteristics, and closure of epiphysis.

(*continued*)

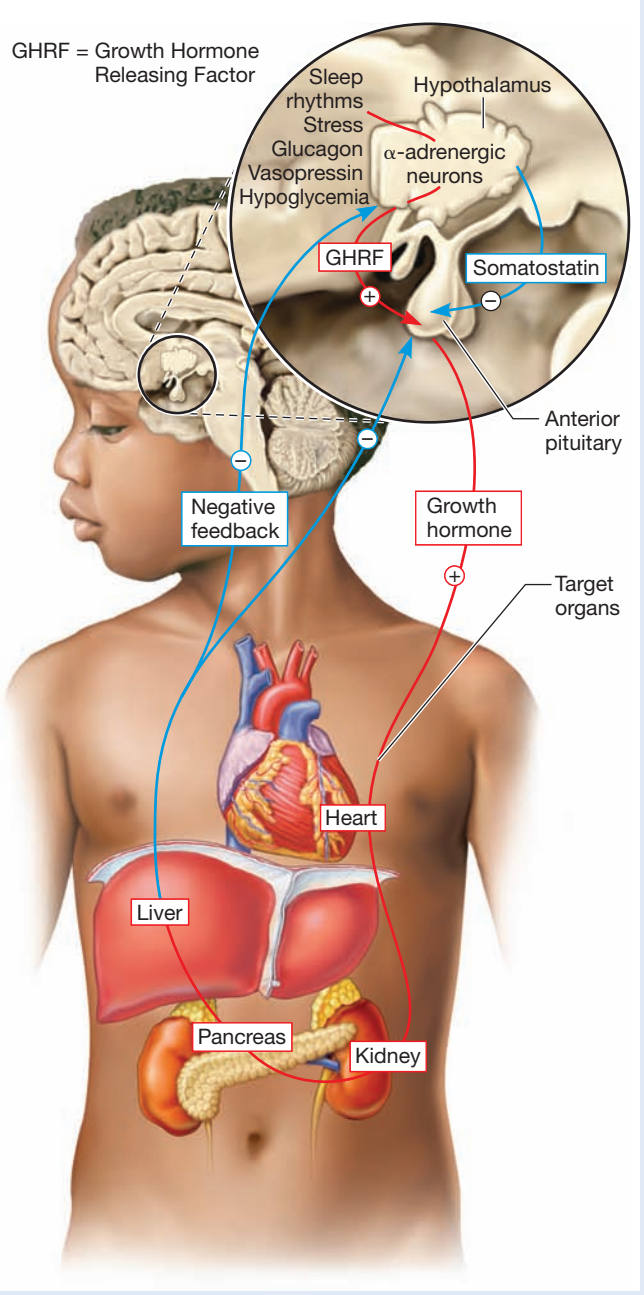

Figure 30–2 **Feedback mechanism in hormonal stimulation of the gonads during puberty.**

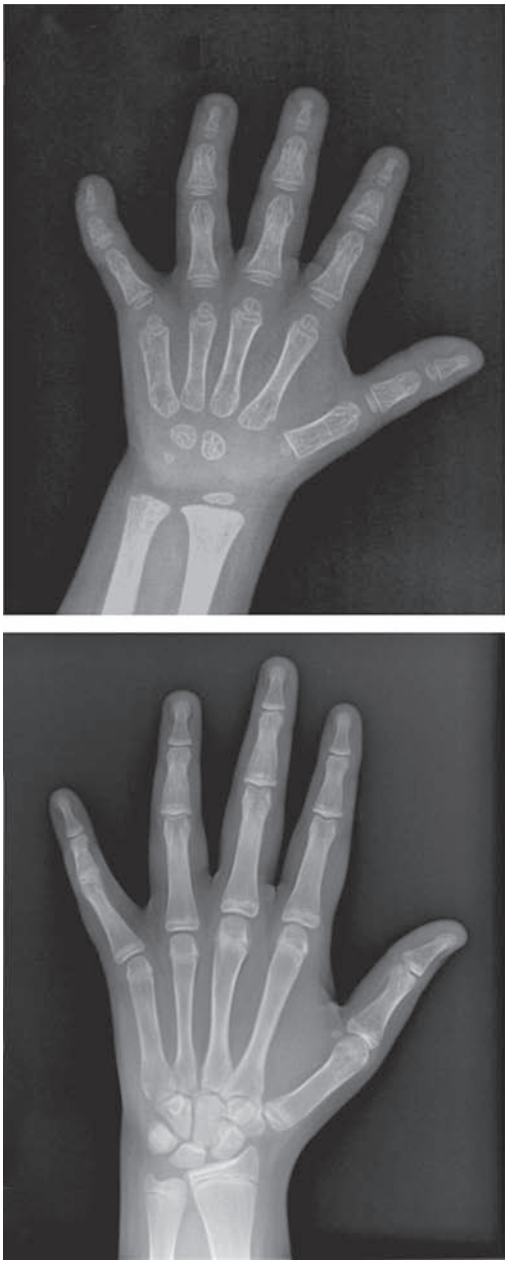
The endocrine system is also responsible for stimulating growth and development during childhood and adolescence. Multiple hormones in the endocrine system, including the growth hormone, thyroid hormone, adrenal and gonadal androgens, and estrogen, are responsible for skeletal growth and maturation. (Carroll & Kerr, 2014). Skeletal maturity can be detected by examining the child's **bone age** (stage of bone ossification) (see *As Children Grow: Bone Age*).

During childhood, the production of sex hormones (estrogen, progesterone, and testosterone) is low. **Puberty** (sexual maturation, lasting an average of 4.5 years) occurs when the gonads begin to secrete increased amounts of the sex hormones estrogen and androgens. At the average age of 9 years in girls and 11 years in boys, the hypothalamus produces increased amounts of gonadotropin-releasing hormone (GnRH). This hormone stimulates the anterior

As Children Grow: **Bone Age**



The radiographs of the hand and wrist of a 3-year-old girl and a 14-year-old girl reveal significant differences in skeletal maturation that are closely tied to physiologic maturation. The 3-year-old has many bones in the hand and wrist that have not fully developed. The secretion of estrogen during puberty has resulted in the development and calcification of secondary ossification centers of most of the bones in the hand and wrist of the 14-year old.

pituitary gland to secrete luteinizing hormone (LH) and follicle-stimulating hormone (FSH). In boys, LH stimulates testosterone production and FSH stimulates sperm production. In girls, LH and FSH stimulate development and maturation of the ova and ovulation. These hormones in turn stimulate the gonads to secrete more sex hormones, resulting in the development of primary and secondary sex characteristics. They also stimulate the genitalia to grow to adult proportions. **Adrenarche** refers to the onset of adrenal androgen production. These adrenal hormones lead to the development of acne, pubic hair, and adult body odor (Bordini & Rosenfield, 2011a). Pubertal development usually follows a specific sequence (breast development, pubic hair growth, and menarche in females; testicular enlargement, pubic hair growth, appearance of spermatozoa in seminal fluid, facial hair, and voice change in males) (Bordini & Rosenfield, 2011b). See Figures 5–28, 5–29, and 5–30 for the development of secondary sexual characteristics in males and females.

Menarche, the onset of menstruation, occurs at an average age of 12.1 years in African American girls and 12.6 years in White girls (Bordini & Rosenfield, 2011b). Menstruation is controlled by several hormones (FSH, LH, estrogen, and progesterone). For 1 to 2 years, cycles are anovulatory of variable duration. In contrast, males begin producing sperm once testicular and penile growth has occurred, during genital stages 3 and 4 (Bordini & Rosenfield, 2011b).

Use *Assessment Guide: The Child With an Endocrine Condition* to perform a nursing assessment. Examples of diagnostic and laboratory tests used to evaluate endocrine conditions are provided in Table 30–2.

Endocrine disturbances result in alterations in metabolism, growth and development, and behavior that may have significant implications for children. If not diagnosed and treated early, these conditions can result in delays in growth and development, intellectual disability (previously called mental retardation), and, occasionally, death. However, treatment, which usually consists of supplementation of missing hormones, adjustment of hormone levels, or dietary measures, allows most children to live a normal life.

Inborn errors of metabolism—inherited biochemical abnormalities of the urea cycle and amino acid and organic acid metabolism—often have a significant impact on the endocrine system's ability to support growth and development. Some chromosomal abnormalities also result in disturbances in growth and sexual development.

TABLE 30–2 Diagnostic Tests and Laboratory Procedures for the Endocrine System

DIAGNOSTIC PROCEDURES	LABORATORY TESTS
ACTH stimulation test	Fasting plasma glucose
Adrenal (ACTH) suppression test	Hemoglobin A_{1c}
Bone age	Hormone levels
Computed tomography (CT)	Insulin-like growth factor (IGF-1) and insulin-like growth factor-binding protein 3 (IGFBP-3)
Fluid deprivation test	Newborn metabolic screening
Karyotype	Provocative growth hormone testing
Magnetic resonance imaging (MRI)	Thyroid antibodies
Thyroid radioactive iodine uptake (RAIU) scan	

Note: See Appendices D and E for more information about these tests and procedures.

ASSESSMENT GUIDE | The Child With an Endocrine Condition

Assessment Focus	Assessment Guidelines
Growth	• Carefully measure weight, length, or height and plot on a growth curve. • Compare measurements at different ages to assess the growth pattern over time and to assess the growth velocity.
Blood pressure	• Assess blood pressure and compare to expected norms for age. See Appendix B.
Facial characteristics	• Inspect the face for unusual features such as a protuberant tongue, protuberant eyes, or moon face.
Neck	• Palpate the neck for an enlarged thyroid or goiter.
Muscles	• Assess strength and muscle tone.
Genitalia and secondary sexual characteristics	• Assess external genitalia for signs of ambiguous genitalia or inappropriate development for age. • Determine the child's stage of development for each characteristic (breast and pubic hair for girls, genital and pubic hair for boys) by comparing to the images in Figures 5–28, 5–29, and 5–30. • Assess the sexual maturity rating with information given in Chapter 5 (Table 5–13). Compare the stage of development to the age of the boy or girl to determine early or delayed onset of puberty.
Body odor	• Assess body odor for unusual smell (e.g., sweet, musty, cheesy, sweaty feet).
Skin	• Assess skin color, noting areas of unusual pigmentation.
Family history	• Assess for family history of metabolic or endocrine disorders.

syndrome, *constitutional growth delay* (delayed pubertal hormone secretion causes a late pubertal growth spurt), chronic renal failure, malnutrition, Cushing syndrome, Down syndrome, inborn error of metabolism, and severe cardiac, pulmonary, immunologic, or gastrointestinal disease. Psychosocial dwarfism is a syndrome of emotional deprivation that causes transient growth hormone deficiency; it is reversed by placing the child in a nurturing environment (Sirotnak, 2013). Refer to Chapter 29 for information about achondroplastic dwarfism.

CLINICAL MANIFESTATIONS

Children with GHD have normal birth weights and length. However, by the age of 1 year, they are below the 3rd percentile on the growth chart. The child characteristically grows at a rate of less than 5 cm (2 in.) per year. Other characteristic findings in infants include hypoglycemic seizures, hyponatremia, neonatal jaundice, pale optic discs, micropenis, and undescended testicles. Children with GHD tend to appear "cherubic" and exhibit youthful facial features, higher pitched voices, delayed dentition, "ripply" abdominal fat, decreased muscle mass, delayed skeletal maturation, and delayed sexual maturation. Slipped capital femoral epiphysis (see Chapter 29) has been associated with growth hormone therapy. Any child receiving growth hormone treatment who complains of hip pain or knee pain, or who manifests a limp, must be evaluated for this disorder (Cooke, Divall, & Radovick, 2011).

Any child whose height is 2 to 3 standard deviations below the mean height for age or whose measurement is falling off the normal growth chart should be evaluated for short stature (Table 30–3). A child whose screening tests reveal low levels of insulin-like growth factor (IGF-1) requires further evaluation by a pediatric endocrinologist. A careful history, physical examination, assessment of pubertal development and unusual facies, and radiologic studies are necessary to rule out familial short stature and constitutional growth delay, which are normal variants; skeletal dysplasias; or psychosocial short stature, which requires further evaluation.

CLINICAL THERAPY

Radiographic imaging of the hand or wrist bone is used to evaluate the stage of bone ossification and thus the bone age of the child. Using standardized norms for bone ossification, it can be determined if the child's chronologic and bone ages match. Significantly delayed (less than the child's age) or advanced (greater than the child's age) bone age may be indicative of the possibility of a systemic chronic disease or hormone abnormality requiring investigation (see *As Children Grow: Bone Age* earlier in this chapter).

Provocative growth hormone testing, in which various medications (arginine, clonidine, glucagon, insulin, L-dopa) are administered to stimulate release of growth hormone, is a diagnostic test that may be used to confirm growth hormone deficiency (Guo, 2013).

For growth hormone deficiency, replacement therapy with growth hormone (GH) is administered to promote growth and development. Growth hormone replacement requires subcutaneous injections 6 to 7 times per week and generally continues for several years until growth is complete. The pediatric endocrinologist adjusts the dosage based on response to treatment (Ferguson, 2011).

The child usually experiences increased growth velocity for the first year of treatment, followed by a gradual decrease in growth for subsequent months or years. Growth should progress at least at the normal rate for age while the child continues on growth hormone treatment. If growth is slower than anticipated, compliance with therapy must be considered before the dosage is increased. Replacement therapy is continued until either the child achieves an acceptable height or growth velocity drops to less than 2 cm (1 in.) per year. Additionally, a bone age of greater than 14 years in girls and 16 years in boys is the criterion to stop treatment. In some cases, the onset of puberty is delayed with GnRH analogs to provide more time for growth hormone therapy to stimulate growth (Parks & Felner, 2016).

Nursing Management

Nursing care consists of monitoring growth, teaching the child and family about the disorder and its treatment, and providing emotional support. Collect blood samples in the manner and time ordered. Carefully measure the child's height and weight and plot them on a growth chart (see Appendix A and the *Clinical Skills Manual* SKILLS).

Teach the parents and child about the GH replacement therapy, preparation and administration of subcutaneous injections, rotating injection sites, potential side effects, and actions to take if any side effects are noticed. Provide the parents with ideas about how to minimize the child's stress associated with daily injections. Give parents educational resources, such as information from the Magic Foundation and the Human Growth Foundation. Replacement therapy is expensive and may not be covered by insurance (Ferguson, 2011).

Children with GHD, especially those whose deficiency is caused by tumors and trauma from radiation or surgery, may have academic problems because of acquired learning disabilities. Before the child enters or returns to school, a comprehensive evaluation should be performed to identify potential problems.

TABLE 30–3 Diagnostic Tests for Short Stature

TEST	PURPOSE RELATED TO SHORT STATURE
IGF-1 (insulin-like growth factor) and IGFBP-3 (insulin-like growth factor-binding protein 3)	Screens for growth hormone deficiency
MRI of the pituitary gland	Detects pituitary malformation or tumor
Provocative growth hormone testing	Tests for growth hormone deficiency
Bone age	Identifies skeletal maturation compared to chronological age
Karyotype (girls)	Detects Turner syndrome
Thyroid function studies	Detects hypothyroidism
ACTH and cortisol levels	Detects other pituitary hormonal deficiencies
Urine creatinine, pH, specific gravity, urea nitrogen, electrolytes	Detects chronic renal failure (see Chapter 26)
Complete blood count and erythrocyte sedimentation rate	Screens for inflammatory bowel disease with anemia
Antigliadin antibodies	Screens for celiac disease

Source: Data from Parks, J. S., & Felner, E. I. (2016). Hypopituitarism. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, & N. F. Schor (Eds.), *Nelson textbook of pediatrics* (20th ed., pp. 2637–2644). Philadelphia, PA: Elsevier; Cooke, D. W., Divall, S. A., & Radovick, S. (2011). Normal and aberrant growth. In S. Melmed, K. S. Polonsky, P. R. Larsen, & H. M. Kronenberg (Eds.), *Williams textbook of endocrinology* (12th ed., pp. 935–1053). Philadelphia, PA: Elsevier Saunders.

Encourage parents and teachers to treat the child in an age-appropriate manner. The child should dress in clothing that reflects chronologic age. Emphasize the child's strengths, support independence, and encourage participation in age-appropriate activities to aid in the development of a positive self-image. Suggest that the child take part in sports in which ability does not depend on size (e.g., swimming, gymnastics, wrestling, ice skating, and martial arts). Identifying positive role models, short people who accomplish their goals, also promotes a positive image. Refer the child for counseling if appropriate.

The best results occur when treatment begins at an early age, before the psychologic effects of short stature become apparent and when attainment of near-normal height is reached. People often treat short children on the basis of their size rather than their age, and such children experience social prejudice about height. Teasing is a common problem. The teenage years may be particularly stressful because of adolescents' characteristic preoccupation with body image.

Growth Hormone Excess (Hyperpituitarism)

Hyperpituitarism, a disorder in which excessive secretion of growth hormone increases the growth rate, is rare in children. If combined with precocious puberty, a tumor of the hypothalamus may be present. Affected children can grow to 7 or 8 feet in height when oversecretion occurs before closure of the epiphyseal plates. If the disorder occurs after closure of the epiphyseal plates, acromegaly occurs.

Because tall stature is valued in our society, assessment of children (particularly males) with accelerated linear growth is often delayed. Any child whose predicted height exceeds that consistent with parental height should be evaluated for possible growth problems and underlying pathologic conditions.

A complete history is obtained, and physical examination and laboratory testing are performed. Increased levels of insulin-like growth factor (IGF-1) establish the diagnosis of hyperpituitarism. Radiologic examination for bone age is obtained to determine if the epiphyseal plates have begun to fuse. Radiologic studies are used to detect a tumor. Thorough evaluation is required to differentiate hyperpituitarism from familial tall stature.

Treatment depends on the cause of the excessive growth and may involve surgical removal of a tumor or pituitary gland (hypophysectomy), radiation therapy, or radioactive implants. High doses of sex steroids are given to close the epiphyseal plates. The child may need lifelong pituitary hormone replacement following surgery.

Nursing Management

Tall stature, like short stature, can be stressful for children. Tall children are often treated as if they are older than their chronologic age. Tall adolescents may have problems with self-image, and girls in particular may worry about their appearance.

Nursing care focuses on teaching the parents and child about the disorder and its treatment, providing emotional support, and, if surgery is required, providing preoperative and postoperative teaching and care (see Chapter 11).

Diabetes Insipidus

Diabetes insipidus is a disorder of the posterior pituitary gland and is defined as an inability of the kidneys to concentrate urine. Two forms of diabetes insipidus occur: central (neurogenic) and nephrogenic diabetes insipidus. Central diabetes insipidus results from inadequate production of vasopressin (antidiuretic hormone), and nephrogenic diabetes insipidus results from ineffective action of vasopressin in the kidneys (Di Iorgi et al., 2012; McHugo & Harden, 2011).

Antidiuretic hormone facilitates concentration of the urine by stimulating reabsorption of water from the distal tubule of the kidney. When ADH is inadequate, the tubules do not resorb, leading to **polyuria** (passage of a large volume of urine in a given period). Therefore, the body is unable to conserve water, resulting in severe dehydration.

The cause of 20% to 50% of cases of central diabetes insipidus is unknown and is classified as being idiopathic (Di Iorgi et al., 2012). Known causes of central diabetes insipidus include brain tumors, brain trauma, central nervous system infection, and neurosurgery (McHugo & Harden, 2011). Genetic nephrogenic diabetes insipidus is not as common as the acquired type, but its presentation is more severe. Acquired nephrogenic diabetes insipidus may be caused by drug toxicity, an adverse drug reaction, or illnesses that impair the ability of the kidneys to concentrate urine (Breault & Majzoub, 2016).

Polyuria and **polydipsia** (excessive thirst) are the cardinal signs of diabetes insipidus. Enuresis is common in children. Polydipsia is the body's attempt to preserve fluid balance. Additional manifestations observed in children with diabetes insipidus include hypernatremia, dilute urine, and dehydration (Table 30–4).

Clinical Tip

During the fluid deprivation test, advise parents that the child will be frustrated and irritable from thirst. No one should drink in front of the child during the testing period. Monitor the child's vital signs, intake, output, and weight carefully (McHugo & Harden, 2011).

TABLE 30–4 Clinical Manifestations of Diabetes Insipidus

CAUSE	CLINICAL MANIFESTATIONS	CLINICAL THERAPY
CENTRAL DIABETES INSIPIDUS		
ADH (vasopressin) deficiency Familial or idiopathic	Polyuria, polydipsia Nocturia, enuresis Thirsty at night Irritable if fluids withheld Constipation, fever, dehydration	Desmopressin acetate
NEPHROGENIC DIABETES INSIPIDUS		
Inherited or acquired Decreased responsiveness of kidneys to ADH (vasopressin)	Polyuria, polydipsia Hypernatremia in neonatal period Dehydration, fever, vomiting Mental status changes	Diuretics High fluid intake Salt- and protein-restricted diet

Although the onset of symptoms is usually sudden, diagnosis is often delayed. Children who can quench their thirst may not complain to parents about symptoms. In infants, symptoms may include irritability, lethargy, vomiting, poor feeding, failure to thrive, and constipation (McHugo & Harden, 2011; Walsh & March, 2013).

In all forms of diabetes insipidus, the urine cannot be concentrated no matter how dehydrated the child becomes. A dehydration episode usually leads to the diagnosis. Serum sodium concentration and osmolality increase rapidly to pathologic levels. Often an unconscious child is admitted to the emergency department with dehydration and hypernatremia.

Initial testing involves serum electrolyte concentrations and a urinalysis including specific gravity and osmolality. Serum osmolality is increased (greater than 300 mOsm/kg), and urine osmolality is decreased (less than 300 mOsm/kg). Urine specific gravity is decreased (less than 1.005), and serum sodium is elevated (greater than 145 mEq/L). A CT scan or MRI may be ordered to visualize the pituitary gland to detect a tumor. A fluid-deprivation test evaluates the level of ADH and helps to confirm the diagnosis (Walsh & March, 2013).

Central ADH deficiency is treated by intranasal or oral desmopressin acetate (DDAVP). The medication reduces urinary output, enabling the child to live a more normal life with a decrease in thirst, urinary output, and nocturia. The dose of DDAVP is based on route of administration, age, and response to therapy (McHugo & Harden, 2011). Nephrogenic diabetes insipidus is treated with thiazide diuretics, which promote sodium excretion and stimulate the proximal tubule to reabsorb water. Indomethacin and amiloride may also be prescribed to have an additive effect on decreased water excretion (Breault & Majzoub, 2016). The child's sodium and potassium levels must be carefully monitored to prevent hypernatremia and hypokalemia (McHugo & Harden, 2011) (see Chapter 18).

Nursing Management

Educate parents about making fluids available to the child as needed, administering DDAVP, obtaining and recording daily weights, measuring intake and output, and recognizing signs of dehydration. Parents may need to weigh diapers to monitor urine output in infants. Cold fluids are often preferred and help relieve thirst. The child's fluid intake will need to be adjusted to prevent dehydration during an illness. Children often wake to drink fluids at night, but infants will need to have fluids provided. Many infants have coexisting brain damage and need nasogastric or gastrostomy feeding to maintain adequate hydration and nutrition. However, care should be taken to avoid the intake of excessive fluid as the child will not be able to excrete the excess water load with DDAVP treatment.

The child with chronic diabetes insipidus should always wear a medical alert identification (tag, bracelet, or necklace) to indicate the presence of the disorder. Partner with the parents and school officials to make arrangements to provide the child unrestricted access to toilet facilities and water.

Syndrome of Inappropriate Antidiuretic Hormone (SIADH)

Syndrome of inappropriate antidiuretic hormone (SIADH) results from an excessive amount of serum ADH. It is seen in children with central nervous system infections, brain tumors, and brain trauma; in children with pulmonary disorders such as pneumonia, asthma, or cystic fibrosis; and in children receiving positive-pressure ventilation. Some medications, including diuretics and chemotherapy, have been associated with SIADH.

Failure of normal feedback mechanisms from the hypothalamus, pituitary gland, and kidney results in excessive secretion of ADH, leading to water reabsorption despite the presence of low serum osmolality. ADH secretion causes increased permeability of the distal renal tubules and collecting ducts and resulting in water reabsorption (Thomas & Fraer, 2014). Elevated ADH also causes suppression of the renin-angiotensin mechanism and sodium excretion. The outcome is **water intoxication** (an abnormal proportion of water to sodium in the extracellular fluid) and hyponatremia.

Signs of SIADH are related to water intoxication and hyponatremia, and include elevated blood pressure, distended jugular veins, crackles in lung fields, weight gain without edema, fluid and electrolyte imbalance, and concentrated urine with decreased urine output. As serum sodium levels continue to fall, lethargy, confusion, headache, altered level of consciousness, seizures, and coma occur because of cerebral edema.

Laboratory findings include a high urine osmolality, low serum osmolality, low serum sodium, high urine sodium, and decreased blood urea nitrogen (Pillai, Unnikrishnan, & Pavithran, 2011; Shoback & Funk, 2011).

Fluids are restricted to prevent further dilution of the blood. Medications include diuretics, demeclocycline to block action of ADH at the renal collecting tubules, and hypertonic saline IV fluids (Robinson & Verbalis, 2011; Shoback & Funk, 2011).

Nursing Management

Nursing care focuses on preventing injury, monitoring fluid balance, administering medications, and managing nutritional intake. Monitor intake and output, serum sodium, urine osmolality, and specific gravity. Educate the parents about the child's fluid restrictions and the hidden sources of water and fluids in foods to help avoid excessive fluid intake.

Teach the importance of checking weight daily and reporting weight gain, which may indicate fluid retention. Refer the family to a registered dietician to assist in identifying hidden sources of water and fluids, such as fruit-flavored ice pops, gelatin, watermelon, and citrus fruit, to prevent excessive fluid intake.

Depending on the cause of the disorder, lifelong medication may be required. If the child is prescribed demeclocycline, emphasize to the family the importance of follow-up care since the drug has nephrotoxic side effects. The child should wear a medical identification alert tag, bracelet, or necklace identifying the disorder and treatment.

Precocious Puberty

Precocious puberty is defined as the appearance of any secondary sexual characteristics before 8 years of age in girls (breast development or pubic hair) and 9 years of age in boys (pubic hair or genital development) (Bordini & Rosenfield, 2011b).

Earlier than expected secretion of the normal hormones responsible for pubertal changes is not usually associated with an endocrine system abnormality (an idiopathic problem). External sources of hormones such as anabolic steroids or estrogen may be identified. Central precocious puberty or true precocious puberty occurs when the hypothalamus is activated to secrete gonadotropin-releasing hormone. Other potential causes of precocious puberty include tumors of the ovary or adrenal gland and a rare genetic condition known as McCune-Albright syndrome (Fuqua, 2013).

Isolated signs of premature sexual development such as **thelarche** (breast development), menarche (vaginal bleeding without other signs of sexual development), and adrenarche (leading to development of pubic and axillary hair) before 8 years of age in girls and 9 years in boys often needs no treatment.

Children with precocious puberty have an advanced bone age (premature skeletal maturation) and may appear unusually tall for their age. However, their growth ceases prematurely as the hormones stimulate closure of the epiphyseal plates, resulting in short stature. Behavioral changes may include mood swings and emotional lability. Early menarche also increases the risk for breast cancer because of prolonged exposure to estrogen (Collaborative Group on Hormonal Factors in Breast Cancer, 2012).

Serum diagnostic studies include LH, FSH, testosterone, or estradiol. Provocative testing includes gonadotropin-releasing hormone (GnRH) stimulation to confirm the diagnosis. Radiologic imaging of the brain, as well as bone age tests, may be performed.

Treatment for central precocious puberty includes a GnRH analog to maintain a constant serum level of GnRH (Fuqua, 2013). Treatment often continues until a more normal age for puberty is reached (e.g., 11 years in girls and 12 years in boys). Simple monitoring of growth patterns may be the only intervention for children closer to the lower than expected age for puberty to begin. Tumors require surgery, radiation, and/or chemotherapy.

Nursing Management

Nursing care should focus on teaching the child and parents about the condition and its treatment, promoting growth, and providing emotional support. Inform the child in age-appropriate terms that the physiologic changes are normal but are occurring at an earlier than usual age. Reassure the child that friends will experience the same stages of development eventually. Emphasize to the family that the child's social, cognitive, and emotional development matches the child's age even though physical development is advanced.

Developing Cultural Competence Onset of Puberty

Differences exist by race in the onset of thelarche in girls of normal weight. Non-Hispanic African American girls and Mexican American girls normally undergo breast development during the seventh year, about 1 year earlier than non-Hispanic White girls (Bordini & Rosenfield, 2011b).

Children with precocious puberty become self-conscious as body changes occur. Provide the child opportunities to express concerns and discuss issues related to body changes. The child may need to practice role-playing as a coping mechanism to manage teasing by other children. Partner with the family to encourage dressing the child in a manner appropriate to the child's chronologic age even though the child may look older. Provide privacy during physical examinations. Advise parents that they may need to discuss issues of sexuality with the child at an earlier age than normal. Refer the child and family for counseling if appropriate.

Teach the family proper medication administration and adherence to the treatment regimen. Determine the family's ability to financially manage the cost of treatment. Assistance in covering the cost of therapy may be available through pharmaceutical companies and third-party payers.

Disorders of Thyroid Function

Hypothyroidism

Hypothyroidism is a disorder in which levels of active thyroid hormones are decreased. It may be congenital or acquired. Congenital hypothyroidism occurs in approximately 1 in 3000 to 1 in 4000 live births worldwide (Seth & Maheshwari, 2013). It is twice as common in females as it is in males. In comparison to White infants, congenital hypothyroidism is less prevalent among Black infants but more prevalent in Hispanic, Asian American, Pacific Islander, and Native American infants (LaFranchi & Huang, 2016).

ETIOLOGY AND PATHOPHYSIOLOGY

Thyroid hormones are important for growth and development and for metabolizing nutrients and energy. When these hormones are not available to stimulate other hormones or specific target cells, growth is delayed and intellectual disability develops.

Congenital hypothyroidism is usually caused by a spontaneous gene mutation, an autosomal recessive genetic transmission of an enzyme deficiency, hypoplasia or aplasia of the thyroid gland, failure of the CNS–thyroid feedback mechanism to develop, or iodine deficiency. Intellectual disability is irreversible if the disorder is not treated.

Acquired hypothyroidism can be idiopathic or result from autoimmune thyroiditis (Hashimoto thyroiditis), late-onset thyroid dysfunction, isolated thyroid-stimulating hormone (TSH) deficiency caused by pituitary or hypothalamic dysfunction, or exposure to drugs or substances such as lithium that interfere with thyroid hormone synthesis. In the case of Hashimoto thyroiditis, the thyroid is infiltrated by lymphocytes that cause an autoimmune reaction and an enlarged thyroid. A genetic predisposition to autoimmune thyroiditis and an autosomal dominant inheritance of thyroid antibodies has been identified (LaFranchi & Huang, 2016).

CLINICAL MANIFESTATIONS

Infants with congenital hypothyroidism have few clinical signs of the disorder in the first weeks of life. Symptoms may include jaundice, thick tongue, hypotonia, umbilical hernia, hoarse cry, dry skin, constipation, and large fontanelles (Zeitler et al., 2014) (Figure 30–3).

Children with acquired hypothyroidism have many of the same signs as adults: decreased appetite; dry, cool skin; thinning hair or hair loss; depressed deep tendon reflexes; bradycardia; constipation; sensitivity to cold temperatures; abnormal menses; and a **goiter** (a nontender enlarged thyroid gland).

Figure 30–3 **Child with congenital hypothyroidism.**

SOURCE: Mediscan/Alamy.

Manifestations unique to children include change in past normal growth patterns with a weight increase, decreased height velocity, delayed bone and dental age, hypotonia with poor muscle tone, and delayed or precocious puberty.

CLINICAL THERAPY

Congenital hypothyroidism is usually detected during newborn screening, which is mandatory in all 50 states (National Newborn Screening and Genetics Resource Center, 2014). Newborn screening has greatly reduced the incidence of intellectual disability associated with this disorder (Shanholtz, 2013). A decreased T_4, normal T_3, and elevated thyroid-stimulating hormone level indicate hypothyroidism. An elevated TSH level indicates that the disease originated in the thyroid, not the pituitary. The two tests used to identify the disorder should occur: (1) before the newborn leaves the hospital and (2) at the first healthcare visit at 1 to 2 weeks of age. Rapid response from the laboratory testing the samples is important to reduce the time to diagnosis and the effects of hypothyroidism on the infant's development.

Levothyroxine is the drug of choice for newborns with congenital hypothyroidism. The recommended starting dose is 10 to 15 mcg/kg per day (Zeitler et al., 2014). The dose is increased gradually as the child grows to ensure a **euthyroid** (thyroid hormones in appropriate balance) state. A pediatric endocrinologist monitors treatment. To ensure an adequate growth rate and prevent intellectual disability, the hormone must be taken throughout life. Periodic evaluation of T_4 and TSH serum levels, bone age, and growth parameters is necessary to assess for signs of excess or inadequate thyroid hormone.

Antithyroid antibodies are measured in children with a goiter and suspected Hashimoto thyroiditis because increased titers of antithyroglobulin and antimicrosomal antibodies are often found.

Children with congenital hypothyroidism that are diagnosed before 3 months of age have the best prognosis for optimal mental development. Children with acquired hypothyroidism usually have normal growth following a period of catch-up growth. Many adolescents with Hashimoto thyroiditis have a spontaneous remission.

Nursing Management

For the Child With Hypothyroidism

Nursing Assessment and Diagnosis

Routine neonatal screening is performed before discharge from the hospital and is often repeated at the infant's first health visit to evaluate levels of circulating thyroid hormones (see the *Clinical Skills Manual* SKILLS).

Record the length or height and weight at each follow-up visit and plot on a growth curve. The child is assessed for signs of inadequate growth to determine if the dose of thyroid hormone needs to be adjusted and to monitor compliance with medication. Conduct developmental screening to detect delays in developmental milestones.

Among the nursing diagnoses that might be appropriate for the child with hypothyroidism are the following (NANDA-I © 2014):

- ***Development: Delayed, Risk for,*** related to delayed initiation of thyroid replacement therapy
- ***Growth: Disproportionate, Risk for,*** related to poor adherence to thyroid hormone therapy
- ***Body Image, Disturbed,*** related to physical changes associated with condition
- ***Fatigue*** related to inadequate dose of thyroid medication

Planning and Implementation

Nursing care focuses on teaching the parents and child about the disorder and its treatment and monitoring the child's growth rate. Explain how to administer thyroid hormone (e.g., tablets can be crushed and mixed in a small amount of formula or applesauce as long as the child gets all of the medication). Advise parents that the child may experience temporary sleep disturbances or behavioral changes in response to therapy. Teach the parents how to assess for an increased pulse rate, which could indicate the presence of too much thyroid hormone, and advise them to report problems such as fatigue, which could indicate an improper drug dose that needs to be adjusted.

Caution parents to dress the child appropriately for the season to prevent hypothermia. Modify the child's diet by increasing the amount of fruits and bulk if constipation is a problem.

Reassure the family that the child has the best chance of normal development when the hormone replacement therapy is given as prescribed. Reinforce the importance of follow-up visits to assess growth rate and response to therapy and to regulate drug dosages as the child grows. Periodic assessments of educational achievement are needed. Even with good control, adolescents have persistent visual-spatial deficits and memory and attention problems. Parents should be informed that therapy will be lifelong and is needed to promote the child's mental development. When the cause is genetic, make a referral for genetic counseling.

Evaluation

Expected outcomes of nursing care of the child with hypothyroidism include the following:

- The child maintains adequate growth of height and weight, following a percentile curve throughout childhood.
- The child's diet contains adequate fruits and bulk to prevent constipation.
- The child's cognitive development is appropriate for age.

Hyperthyroidism

Hyperthyroidism occurs when thyroid hormone levels are increased, resulting in excessive levels of circulating thyroid hormones. Graves disease is the most common cause of hyperthyroidism in children, occurring more often in females and in children ages 11 to 15 years (Gastaldi et al., 2014).

ETIOLOGY AND PATHOPHYSIOLOGY

Graves disease is an autoimmune disorder. Immunoglobulins produced by the B lymphocytes stimulate oversecretion of thyroid hormones, resulting in the clinical symptoms. It has a high familial incidence.

Other less common causes of hyperthyroidism result from thyroiditis and thyroid hormone–producing tumors, including thyroid adenomas and carcinomas, and pituitary adenomas. Congenital hyperthyroidism can occur in infants of mothers with Graves disease as a result of transplacental transfer of immunoglobulins. This condition generally resolves by 6 to 12 weeks of age but can last longer (Huang & LaFranchi, 2016).

CLINICAL MANIFESTATIONS

Signs and symptoms are caused by hyperactivity of the sympathetic nervous system and may include an enlarged, nontender thyroid gland (goiter), prominent or bulging eyes (**exophthalmos**) (Figure 30–4), eyelid lag, tachycardia, nervousness, increased appetite with weight loss, emotional lability, moodiness, heat

Figure 30–4 **Exophthalmos in an adolescent with Graves disease.**

SOURCE: Biophoto Associates/Science Source.

intolerance, hypertension, hyperactivity, irregular menses, insomnia, tremor, and muscle weakness (Bauer, 2011; Gastaldi et al., 2014). The thyroid gland may be slightly enlarged or grow to 3 to 4 times its normal size; feel warm, soft, and fleshy; and have an auditory bruit on auscultation. Onset is subtle, and the condition often goes unrecognized for 1 to 2 years.

Children with Graves disease usually have difficulty concentrating, behavioral problems, and declining performance in school. They become easily frustrated in the classroom and overheated and fatigued during physical education class. Children with this disorder find it difficult to relax or sleep. These symptoms usually prompt parents to seek medical treatment for the child.

The most serious complication of hyperthyroidism is severe **thyrotoxicosis**, also called *thyroid crisis* or *thyroid storm*. It is a life-threatening emergency resulting from extreme hyperthyroidism, in which elevated circulating levels of TH result in a hypermetabolic state. Symptoms include muscle weakness, diaphoresis, tachycardia, tremor, palpitations, diarrhea, irritability, nervousness, and anxiety (Bahn et al., 2011; Bauer, 2011; Fitzgerald, 2015).

CLINICAL THERAPY

Diagnostic studies include laboratory evaluation of serum TSH, T_3, and T_4 levels and a thyroid scan. T_3 and T_4 levels are markedly elevated, whereas the TSH level is decreased. Serum studies are also performed to detect thyroid autoantibodies anti-TG (antithyroglobulin) and anti-TPO (antiperoxidase), usually present in Graves disease and Hashimoto thyroiditis. A thyroid scan is performed to identify nodules or to confirm the high uptake of radioactive iodine associated with Graves disease.

The goal of clinical therapy is to inhibit excessive secretion of thyroid hormones. Treatment may include medication therapy, radiation therapy, or surgery. Medication therapy is most often the initial treatment, but compliance is often a problem because of side effects. Methimazole (Tapazole) and propylthiouracil (PTU) are antithyroid drugs that are used in children with hyperthyroidism. Because of the concern for severe liver disease with the administration of PTU, current recommendations are that children with hyperthyroidism receive methimazole instead (Bauer, 2011; Huang & LaFranchi, 2016; Rivkees, 2014).

Symptoms usually improve within weeks of starting treatment. Adjunct therapy with beta-adrenergic blocking agents such as propranolol or atenolol may be administered to relieve symptoms of tremors, tachycardia, lid lag, and excessive sweating (Bahn et al., 2011; Huang & LaFranchi, 2016).

Less than 30% of children achieve remission after a 2-year course of treatment with medication. Radiation therapy or thyroidectomy are other options if medication therapy is not effective (Leger et al., 2012). Thyroidectomy (removal of most of the thyroid) provides an immediate cure and avoids radiation and possible long-term complications of radioactive iodine. Removal of the thyroid gland results in hypothyroidism. Complications of thyroidectomy include hemorrhage, hypocalcemia, and damage to the laryngeal nerve paresis (Rivkees, 2014).

Nursing Management

For the Child With Hyperthyroidism

Nursing Assessment and Diagnosis

Assess the child's vital signs, as blood pressure and pulse may be elevated. Keep a record of food intake. Accurate measurement and recording of height and weight are important to establish baselines and identify patterns of growth. Observe the child's behavior, activity, and level of fatigue.

Common nursing diagnoses for the child with hyperthyroidism include the following (NANDA-I © 2014):

- ***Thermoregulation, Ineffective,*** related to illness and excessive activity of the sympathetic nervous system
- ***Nutrition, Imbalanced: Less than Body Requirements,*** related to high metabolic needs
- ***Body Image, Disturbed,*** related to physical changes caused by illness (prominent eyes, excessive perspiration, and tremors)
- ***Fatigue*** related to hypermetabolic state and sleep deprivation

Planning and Implementation

Nursing care focuses on teaching the child and parents about the disorder and its treatment, promoting rest, providing emotional support, and, if the child needs surgery, providing preoperative and postoperative teaching and care. Promote increased caloric intake by providing five or six moderate meals per day. Encourage the child and family to express their feelings and concerns about the disorder. Pointing out even slight improvements in the child's condition increases adherence with therapy.

Children with hyperthyroidism are easily fatigued. Rest periods should be scheduled at school and home and physical activities kept to a minimum until symptoms resolve. Encourage parents to provide a cool environment and allow the child to wear fewer clothes until symptoms subside.

Children who have partial or total removal of the thyroid gland receive antithyroid drugs, such as iodine, for approximately 2 weeks before surgery to reduce the vascularity and size of the thyroid gland and to decrease the risk of thyroid storm.

Teach the child and parents about drug therapy and instruct parents to watch for side effects of antithyroid drugs, including fever, urticaria, and lymphadenopathy. Provide preoperative teaching (see Chapter 11). Young children in particular may be fearful about having their throat "cut."

Postoperatively, elevate the head of bed to 30 degrees to promote patent airway. A tracheostomy kit, suction supplies, and IV calcium gluconate should be immediately available for emergency treatment of hypocalcemia and respiratory distress. If thyroidectomy is performed, thyrotoxicosis develops, and it does not immediately resolve because the half-life of T_4 is 7 to 8 days. Antithyroid medications should be slowly tapered (Sharma, 2014).

Teach the family about the need for lifelong thyroid hormone replacement if radiation or surgery is performed. The child should wear a medical alert identification bracelet, tag, or necklace. Make sure the child is monitored regularly to ensure that the T_4 level is adequate to sustain growth.

Evaluation

Expected outcomes of nursing care for the child with hyperthyroidism include the following:

- The child achieves balanced thermoregulation.
- The child participates in daily activities without experiencing fatigue.
- The child demonstrates a positive body image.

Disorders of the Parathyroid

Children usually have four parathyroid glands located posterior to the thyroid gland. Their primary function is to work in conjunction with vitamin D to regulate total body calcium.

Hyperparathyroidism

Primary hyperparathyroidism, rare during childhood, may result from a tumor (adenoma) or hyperplasia (Doyle, 2016a). Secondary hyperparathyroidism is due to disease outside of the parathyroid gland, leading to excessive secretion of parathyroid hormone. This is commonly seen in chronic renal failure when the kidneys are unable to reabsorb calcium, causing low serum calcium levels and stimulating continual secretion of parathyroid hormone (Kemper & van Husen, 2014). See Chapter 26.

At any age, symptoms of primary hyperparathyroidism may include bone pain, nephrolithiasis (kidney stones), and pathologic bone fractures. For primary hyperparathyroidism, unilateral surgical parathyroid exploration is recommended to remove the affected gland and biopsy the other gland on the same side. If bilateral disease is suspected, both sides are explored surgically (Belcher, Metrailer, Bodenner, et al., 2013). Treatment of secondary hyperparathyroidism focuses on prevention of hypercalcemia using vitamin D replacement and phosphorus binders (Kemper & van Husen, 2014).

Nursing Management

Nursing care centers on fluid management and electrolyte monitoring. In children who require surgery, assess for respiratory distress and a potential airway obstruction due to edema and a potential hematoma around the tracheal space. Monitor for signs of infection.

Following surgery, educate the child and parents to recognize signs of hypocalcemia and to provide appropriate amounts of calcium supplementation. After diagnosis or after surgical intervention, follow-up is important to monitor serum calcium and phosphorus levels to detect persistence of hyperparathyroidism.

Hypoparathyroidism

Primary hypoparathyroidism is rare, but it may result from congenital disorders (parathyroid aplasia, DiGeorge syndrome), surgical removal of the parathyroid glands (e.g., parathyroid adenoma, thyroidectomy), disease processes that destroy the parathyroid glands (Wilson disease, hemochromatosis), or medications (e.g., aluminum, asparagine, doxorubicin, cytosine, and arabinoside). Hypoparathyroidism can also be idiopathic. The primary result is hypocalcemia and hyperphosphatemia.

Infants may display hyperirritability, muscle rigidity, seizures, vomiting, abdominal distention, apneic episodes, intermittent cyanosis, or twitching. Muscle pain and cramps may progress to numbness, stiffness, and tingling of the hands and feet. A positive **Chvostek sign** (spasm of facial muscles after tapping facial nerve) may be present. Tetany and convulsions may occur with hypocalcemia (Doyle, 2016b).

Serum calcium and PTH levels are low and serum phosphorus is elevated. Radiographs often demonstrate increased bone density. Oral calcitriol and calcium are prescribed. Foods with high phosphorus content (dairy products and eggs) are limited (Doyle, 2016b).

Nursing Management

Assess and stabilize the airway, breathing, and circulation. In the acute care setting, children should be placed on a cardiorespiratory monitor. Maintain seizure precautions until normal serum calcium levels are attained. Obtain intravenous access and administer calcium supplementation as ordered.

SAFETY ALERT!

Dilute intravenous calcium per hospital protocol. Infiltration of IV calcium can cause extravasation and tissue sloughing. Always check the patency of the IV prior to administration. Monitor ECG during administration. Evaluate for hypocalcemia and hypercalcemia after administration.

Partner with the family to ensure their understanding of the need for calcium supplementation and reduced intake of phosphorus. Teach the family that periodic monitoring of calcium levels is important. Inform the family that hypoparathyroidism may require lifelong therapy.

Disorders of Adrenal Function

Cushing Syndrome and Cushing Disease

Cushing syndrome, also called *adrenocortical hyperfunction*, is characterized by a group of symptoms resulting from excess blood levels of glucocorticoids (especially cortisol). The most common cause of Cushing syndrome is the prolonged administration of glucocorticoid hormones (White, 2016a). Cushing disease is a type of Cushing syndrome and is caused by a pituitary tumor (Shah & Lila, 2011). During infancy most cases of endogenous Cushing disease are caused by a functioning adrenocortical tumor. The most common cause of endogenous Cushing syndrome in children older than 7 years of age is Cushing disease in which a pituitary tumor (adenoma) secretes excessive ACTH. This leads to bilateral adrenal hyperplasia (White, 2016a). The remainder of this discussion will focus on the child with Cushing syndrome caused by a pituitary tumor (Cushing disease). See *Clinical Tip* and *Safety Alert!* for discussions of Cushing syndrome caused by corticosteroid administration.

Clinical Tip

Cushingoid features occur most often in children receiving high doses of corticosteroids or corticosteroids over a prolonged period of time. Cushingoid features may develop in a shorter time than occurs with Cushing disease. Corticosteroids suppress adrenal function when administered long term. These children have exogenous Cushing syndrome and are at increased risk of hypertension, hyperglycemia, weight gain, linear growth retardation, and fractures (White, 2016a). These children may also exhibit mood swings and are at increased risk for infection (Wilson, Shannon, & Shields, 2016).

SAFETY ALERT!
Caution should be exercised with the use of topical steroid creams in children. Cases of exogenous Cushing syndrome have been reported with the prolonged use of these agents in the treatment of diaper dermatitis in infants and young children (Ho, Loke, Lim, et al., 2014).

Obesity is common in children with Cushing syndrome. Excessive weight gain is followed by slowed linear growth. The child develops the characteristic cushingoid features, which include a rounded (moon) face with prominent cheeks. Additional manifestations include hirsutism, acne, deepening of the voice, and hypertension (White, 2016a). Older children may also experience delayed puberty, irregular menstrual periods, headaches, weakness, pathologic fractures, emotional problems, and hyperglycemia (Pluta, Burke, & Golub, 2011; White, 2016a).

Diagnosis is based on characteristic physical findings and laboratory values, including increased 24-hour urinary levels of free cortisol and elevated nighttime salivary cortisol level. The child will also have an abnormal glucose tolerance test (White, 2016a). See Appendix D for laboratory values.

The adrenal-suppression test using an 11 p.m. dose of dexamethasone reveals that adrenal cortisol output is not suppressed overnight as would occur normally in children. Computed tomography (CT) and magnetic resonance imaging (MRI) are used to detect the specific location of tumors in the adrenal and pituitary glands.

Surgical removal of the pituitary adenoma is the current treatment of choice when this is the cause of Cushing syndrome. Irradiation of the pituitary is performed when surgical removal of the adenoma does not substantially reduce cortisol levels. Bilateral removal of the adrenal glands may be necessary in some cases to stop the excessive secretion of cortisol. Lifelong hormone replacement is required when both adrenal glands are removed (Pluta et al., 2011; White, 2016a).

Nursing Management

Nursing assessment includes monitoring the child's vital signs, fluid status, nutritional status, and weight. Additional assessment includes monitoring muscle strength and endurance during hospital play activities.

Teach the child and family about the disorder and its treatment. For children undergoing surgery, provide preoperative and postoperative teaching and care. Answer any questions the child and family may have and explain all laboratory and diagnostic tests. Explain to parents that the child's cushingoid appearance is reversible with treatment. Refer to Chapter 24 for general nursing care of the child with cancer. Provide nutritional guidance or refer the child and parents to a registered dietician to promote maintenance of an appropriate weight. Encourage the child to discuss feelings regarding changes in physical appearance. Assist the child and family to identify effective coping strategies.

For children who need cortisol replacement therapy following the surgical removal of both adrenal glands, administering the medication early in the morning or every other day causes fewer symptoms and mimics the normal diurnal pattern of cortisol secretion. Cortisol replacement in the postoperative period must be explained carefully to the parents. Hydrocortisone (Cortef, Solu-Cortef, cortisone acetate) is available in liquid, tablet, or injectable form. Parents may need to crush the tablet and mix with a small amount of applesauce, but the entire dose of medication must be taken. The oral preparations of cortisone have a bitter taste and can cause gastric irritation. Giving the dose at mealtimes and using antacids between meals help reduce these side effects. Teach parents how and when to administer the injectable form—usually when the child is vomiting, has diarrhea, or cannot take the oral medication. Failure to give medication when the child is ill may lead to severe illness and cardiovascular collapse.

Congenital Adrenal Hyperplasia

Congenital adrenal hyperplasia (CAH) is an autosomal recessive disorder occurring in 1 in 10,000 to 1 in 20,000 births (Boyse, Gardner, Marvicsin, et al., 2014). CAH is considered to be an inborn error of metabolism.

ETIOLOGY AND PATHOPHYSIOLOGY

Approximately 90% to 95% of children with congenital adrenal hyperplasia have a deficiency in 21-hydroxylase (Hird, Tetlow, Tobi, et al., 2015). Children with CAH have insufficient production of aldosterone and cortisol and an overproduction of androgen (Boyse et al., 2014; Hird et al., 2015).

Of the two classic forms of the disorder, 75% are salt-losing, caused by aldosterone deficiency and overproduction of androgen, and 25% are non–salt-losing with **virilization** (the production of masculine secondary sexual characteristics in females). In all forms, increased secretion of ACTH occurs in response to diminished cortisol levels (Nimkarn, Lin-Su, & New, 2011).

Families Want to Know

Hydrocortisone Administration

Teach the family the following tips regarding hydrocortisone administration:

- Always give the medication at the times prescribed since the schedule follows the body's normal cortisol release pattern.
- Never abruptly discontinue the medication.
- Have the child wear a medical alert ID.
- If the child has vomiting or diarrhea and is unable to take the medication by mouth, administer the injections to replace oral doses as instructed and notify the healthcare provider immediately. Higher doses of hydrocortisone are needed when the child is ill.
- Always have injectable hydrocortisone available at home, at school, and everywhere the child travels. An emergency kit should be available at all times to supply cortisol to the child during acute illnesses and stressful situations. Check expiration dates frequently and maintain current medications in the emergency kit.

During fetal development the lack of cortisol triggers the pituitary to continue secretion of ACTH. This in turn stimulates overproduction of the adrenal androgens. Virilization of the female external genitalia begins in week 10 of gestation. If untreated, the overproduction of androgens results in accelerated height, early closure of the epiphyseal plates, and premature sexual development with both pubic and axillary hair.

CLINICAL MANIFESTATIONS

Congenital adrenal hyperplasia is the most common cause of **pseudohermaphroditism** (ambiguous genitalia) in newborn girls (see Figure 30–5). The female baby is born with an enlarged clitoris and partial or complete labial fusion. Females who are severely virilized may be mistaken for males with cryptorchidism, hypospadias, or micropenis (see Chapter 26). The uterus, ovaries, and fallopian tubes are normal. The male newborn may look normal at birth or may have a slightly enlarged penis and hyperpigmented scrotum. The boy may have tall stature and an adult-sized penis by school age, but the testes are appropriately sized for age. Partial enzyme deficiency produces less obvious symptoms. Precocious puberty, tall stature for age, acne, and excessive muscle development may be noted in both males and females as the child grows. As a result of early epiphyseal fusion, adult stature is shorter.

Signs of adrenal insufficiency may be the first indication of the disorder. Recurrent vomiting, dehydration, weakness, metabolic acidosis, hypotension, hypoglycemia, hyponatremia, and hyperkalemia are characteristic signs of the salt-wasting form of the disorder (White, 2016b).

CLINICAL THERAPY

Diagnosis in infants and children is usually confirmed by laboratory evaluation of the serum 17-hydroxyprogesterone (17-OHP) level (Hird et al., 2015). Routine newborn screening for congenital adrenal hyperplasia is performed in all 50 states (National Newborn Screening and Genetics Resource Center, 2014). Prenatal diagnosis is available. In instances of ambiguous genitalia, a karyotype determines the infant's gender (see Chapter 3). Ultrasonography may be used to visualize pelvic structures.

In the salt-wasting form of the disorder, the child may have hyponatremia, hyperkalemia, acidosis, hypoglycemia, a high urine sodium level, and low serum and urinary aldosterone levels. Serum concentrations of testosterone in girls and androstenedione in boys and girls are elevated in affected infants. Measurement of ACTH and 17-hydroxyprogesterone levels reveals high readings, while the serum cortisol level is inappropriately low in comparison to ACTH (White, 2016b).

Figure 30–5 **Newborn girl with ambiguous genitalia.**

SOURCE: Courtesy of Patrick C. Walsh, MD.

The goal of treatment is to suppress adrenal secretion of androgens by replacing deficient hormones. This is accomplished by the lifelong use of oral glucocorticoids (dexamethasone, prednisone, or hydrocortisone). The glucocorticoid replacement reduces secretion of ACTH, which had overstimulated the adrenal cortex. As a result, excessive adrenal androgen production is suppressed. The dose is individualized by monitoring growth parameters, bone age, and hormone levels. If the infant has the salt-wasting form of the disorder, salt is added to the infant's formula, and a mineralocorticoid is given to replace the missing hormone. Hormone dosage must be doubled or tripled during acute illnesses or injury and for surgery. Injectable hydrocortisone is used for severe stress. Generally, there are no side effects to the hormone; however, elevated doses can result in hypertension and growth impairment. Adrenalectomy is recommended only in cases when medical therapy is ineffective (Sharma & Seth, 2014; White, 2016b).

Reconstructive surgery of the enlarged clitoris is often performed on girls during the first year of life; however, some centers support waiting until adolescence, allowing the girl to participate in the decision for surgery.

Nursing Management

For the Child With Congenital Adrenal Hyperplasia

Nursing Assessment and Diagnosis

Assess the infant and child for signs of dehydration, electrolyte imbalance, and hypovolemic shock in the salt-wasting form of the disease (see the *Clinical Skills Manual* SKILLS). Monitor the airway, breathing, circulation, and responsiveness. Assess vital signs and peripheral perfusion (capillary refill, distal pulses, color and temperature of the extremities) frequently to detect early changes in condition such as hypovolemia.

Assess the parents' emotional response to a child with ambiguous genitalia and a chronic condition. Explore their values and beliefs regarding gender roles and sexuality while awaiting results of the karyotype.

Nursing diagnoses for the child with congenital adrenal hyperplasia might include the following (NANDA-I © 2014):

- ***Parenting, Impaired,*** related to a child with undetermined gender identity
- ***Caregiver Role Strain*** related to care of a child with a chronic, potentially life-threatening condition
- ***Fluid Volume: Deficient, Risk for,*** related to failure of regulatory mechanisms and excess excretion of salt by the kidneys
- ***Growth: Disproportionate, Risk for,*** related to accelerated growth and premature closure of epiphyseal plates

Planning and Implementation

Nursing care of the newborn with CAH focuses on teaching parents about the disorder and its treatment, offering emotional support, and providing preoperative and postoperative teaching for parents of infants undergoing reconstructive surgery. The administration of glucocorticoids and mineralocorticoids must be carefully controlled.

It is often difficult for parents to accept that their infant, whose genitalia look male, is really female. Reassure parents that with medication and surgery, the genitalia assume a female appearance and all organs necessary for future childbearing are usually functional. Several surgeries may be performed before 2 years of age and then during adolescence to dilate the vagina. Because of the risk for adrenal insufficiency, the child will most likely be hospitalized for surgery rather than having outpatient surgery.

Nurses can assist parents in educating the child's siblings, grandparents, other family members, and childcare workers about the condition. In the newborn nursery, the infant should be referred to as "your beautiful infant," not "your son" or "your daughter," until gender identity is confirmed.

Inform parents that genetic counseling should be provided for the child during adolescence. Inform parents considering a future pregnancy that prenatal testing may detect congenital adrenal hyperplasia in the fetus. Refer the family for counseling if indicated.

COMMUNITY-BASED NURSING CARE

Teach parents about the special problems that develop in the salt-wasting form of the disease during acute illness. Explain the medication regimen and help the family develop an emergency care plan. The child should wear a medical alert identification. Teach parents how to administer intramuscular injections of hydrocortisone. If injectable hydrocortisone is not available, the child needs urgent treatment in an emergency department. The child may become dehydrated quickly and need intravenous fluid and electrolyte replacement in addition to higher doses of hydrocortisone.

Evaluation

Expected outcomes of nursing care for congenital adrenal hyperplasia include the following:

- Parent–newborn attachment is achieved.
- The child maintains fluid volume balance.
- The child achieves age-appropriate growth and developmental milestones.
- The parents demonstrate understanding of treatment and respond appropriately when injectable medication is needed.

Adrenal Insufficiency (Addison Disease)

Adrenal insufficiency, also known as *Addison disease*, is a rare disorder in childhood characterized by a deficiency of glucocorticoids (cortisone) and mineralocorticoids (aldosterone). The lack of glucocorticoids affects the body's ability to handle stress. The majority of cases of Addison disease are caused by an autoimmune process. Other causes include infection, hemorrhage, medication use, and metastatic cancer (Michels & Michels, 2014).

Adrenal insufficiency usually develops slowly as the adrenal glands deteriorate. Symptoms generally worsen over a period of years. The early signs may not be noticed initially but include weakness, fatigue, weight loss, and gastrointestinal symptoms such as nausea, vomiting, diarrhea, constipation, and abdominal pain. Other symptoms include hyperpigmentation, hypotension, dizziness, joint pain, salt cravings, and hypoglycemia (Michels & Michels, 2014; National Endocrine and Metabolic Diseases Information Service, 2014).

CLINICAL THERAPY

The ACTH stimulation test is used to determine if the levels of cortisol are adequate. Serum cortisol is measured in the early morning. Low levels of serum cortisol are associated with adrenal insufficiency. The diagnostic workup also includes a complete blood count, serum electrolytes, and thyroid function tests. Hyponatremia and hyperkalemia are common in Addison disease. A CT scan may be used to visualize the adrenal glands (Ficorelli, 2013).

Treatment involves replacement of the deficient hormones with an oral glucocorticoid such as hydrocortisone, prednisone, or dexamethasone. Fludrocortisone acetate (Florinef), a mineralocorticoid, is given for aldosterone deficiency (Ficorelli, 2013).

Adrenal crisis (also called *Addisonian crisis* and *acute adrenal insufficiciency*) may be caused by stressors such as infection, surgery, trauma, vomiting, and diarrhea. Noncompliance with the treatment plan may also be a precipitating factor (Ficorelli, 2013). The crisis is treated with aggressive fluid resuscitation, intravenous glucose, and intravenous glucocorticoids such as hydrocortisone. Children will also need increased doses of steroids during periods of increased physiologic stress, such as surgery, stressful procedures, and febrile illnesses. In these cases, the dose of hydrocortisone should be tripled and given every 6 to 8 hours while the stressor is present. Injectable hydrocortisone should always be available in case the child is vomiting or unable to take oral fluids (Speiser & Wilson, 2014).

Nursing Management

Nursing management focuses on restoring hemodynamic homeostasis in the child with Addison disease who is acutely ill. Educating the child and parents about the disorder, providing emotional support, and caring for the child during acute episodes are other aspects of nursing management. See the earlier discussion of congenital adrenal hyperplasia for further detail.

Pheochromocytoma

Pheochromocytoma is a tumor that arises from the adrenal gland. Tumors that are extra-adrenal with no anatomic connection are called *paragangliomas* (Mishra, Mehrotra, Agarwal, et al., 2014). In most cases, these tumors are benign and curable. They can occur in a familial pattern (autosomal dominant trait) with a male-to-female ratio of 3:2. Most tumors diagnosed in children are identified between the ages of 6 and 14 years; however, this accounts for only 10% of these tumors as most are identified during adult years (White, 2016c). Pheochromocytomas may also be associated with neurofibromatosis (see Chapter 27).

The tumor causes an excessive release of catecholamines. Clinical manifestations include hypertension, palpitations, sweating, anxiety, tremors, and headache for those with symptomatic pheochromocytoma. Twenty to 30% of these tumors are detected incidentally without a history of symptoms (Shuch, Ricketts, Metwalli, et al., 2014)

CLINICAL THERAPY

Diagnosis is based on biochemical studies measuring catecholamines in the blood and urine. Radiologic imaging with CT or MRI is used to provide the location of the tumor.

The treatment of choice is curative surgical removal of all identified tumors; however, the procedure is dangerous and may result in pheochromocytoma crisis. Removal of the tumor during surgery may cause a release of stored epinephrine and

norepinephrine, leading to elevated blood pressure and changes in heart rate (pheochromocytoma crisis). If this occurs, alpha-adrenergic blocking agents are administered.

Medications to control hypertension, tachycardia, and catecholamine release are given for 7 to 21 days before surgery (Tsirlin, Oo, Sharma, et al., 2014). Plasma catecholamines are used to measure the effectiveness of the preoperative adrenergic blockade. Postoperatively, for several days, a 24-hour urine collection is measured for catecholamines to determine if all tumor sites were removed. With successful removal of all tumor sites, the prognosis is generally good. Follow-up is important to assess for recurrence.

Nursing Management

Nursing care is mainly supportive. Provide preoperative and postoperative teaching and care (see Chapter 11). Preoperatively, monitor vital signs and observe for signs of complications associated with pheochromocytoma crisis. Administer antihypertensives and watch for any signs of hyperglycemia, as discussed later in this chapter. Postoperatively, the child may be managed initially in an intensive care unit. Monitor blood pressure and glucose levels. Hypoglycemia and hypotension may occur following the withdrawal of excessive amounts of catecholamines. Observe for changes in neurologic status, respiratory distress, and signs of shock. Lifelong follow-up care with screening for hypertension and increased urinary catecholamine levels is required as symptoms recur if the child has other tumors not yet detected that activate at a later age (Tsirlin et al., 2014; White, 2016c).

Disorders of Pancreatic Function

Diabetes Mellitus

Diabetes mellitus, the most common metabolic disease in children, is a disorder of hyperglycemia resulting from defects in insulin secretion, insulin action, or both, leading to abnormalities in carbohydrate, protein, and fat metabolism (American Diabetes Association [ADA], 2014a). There are two main types of diabetes. Most children have immune-mediated type 1 diabetes, formerly called *insulin-dependent diabetes mellitus* or *juvenile diabetes*.

Type 1 Diabetes

In the United States, approximately 1 in every 400 to 600 children and adolescents have type 1 diabetes (Monaghan, Hoffman, & Cogen, 2013). According to the SEARCH for Diabetes in Youth Study, an estimated 18,436 people less than 20 years of age were diagnosed during 2008 to 2009. Non-Hispanic White children and adolescents had a higher incidence of new-onset type 1 diabetes than other groups (Centers for Disease Control and Prevention [CDC], 2014).

ETIOLOGY AND PATHOPHYSIOLOGY

Type 1 diabetes results from destruction of pancreatic islet beta cells, which fail to secrete insulin. The body becomes dependent on exogenous sources of insulin. Type 1 diabetes is a multifactorial disease caused by autoimmune destruction of insulin-producing pancreatic beta cells in individuals who are genetically predisposed (ADA, 2014a).

Type 1 diabetes has familial tendencies but does not show any specific pattern of inheritance. The number of autoantibodies helps predict the risk of developing type 1 diabetes. For children with one antibody, the risk is only 10% to 15%, while those with three or more antibodies have a risk of 55% to 90% (Marcdante & Kliegman, 2015). The child inherits a susceptibility to the disease rather than the disease itself. It is believed that an event such as a virus or other environmental factors trigger the inflammatory process, resulting in development of islet cell serum antibodies. These antibodies can be detected in the blood months to years before the onset of beta cell destruction (Marcdante & Kliegman, 2015).

Insulin helps transport glucose into the cells so that the body can use it as an energy source. It also prevents the outflow of glucose from the liver to the general circulation. Environmental factors such as enteroviruses or toxins are believed to lead to an autoimmune destruction of the beta cells in the islets of Langerhans (see *Pathophysiology Illustrated: Mechanism of Diabetes Mellitus*). Antigens are generated, leading to production of antibodies that indicate ongoing destruction of the islet cells. Chronic immune-mediated destruction of the beta cells continues over a period of time. Symptoms of type 1 diabetes are evident when approximately 90% of the beta cells have been destroyed (Craig et al., 2014)

As the secretion of insulin decreases, the blood glucose level rises and the glucose level inside the cells decreases. When the renal threshold for glucose (180 mg/dL) is exceeded, **glycosuria** (abnormal amount of glucose in the urine) occurs as a result of osmotic diuresis (Svoren & Jospe, 2016). Fluids follow the highly osmotic glucose and water is excreted in large volumes of urine (polyuria).

When glucose is unavailable to the cells for metabolism, free fatty acids provide an alternate source of energy. The liver metabolizes fatty acids at an increased rate, producing acetyl coenzyme A (CoA). The by-products of acetyl CoA metabolism (ketone bodies) accumulate in the body, resulting in a state of metabolic acidosis, or ketoacidosis. (Refer to Chapter 18 for a discussion of metabolic acidosis.)

CLINICAL MANIFESTATIONS

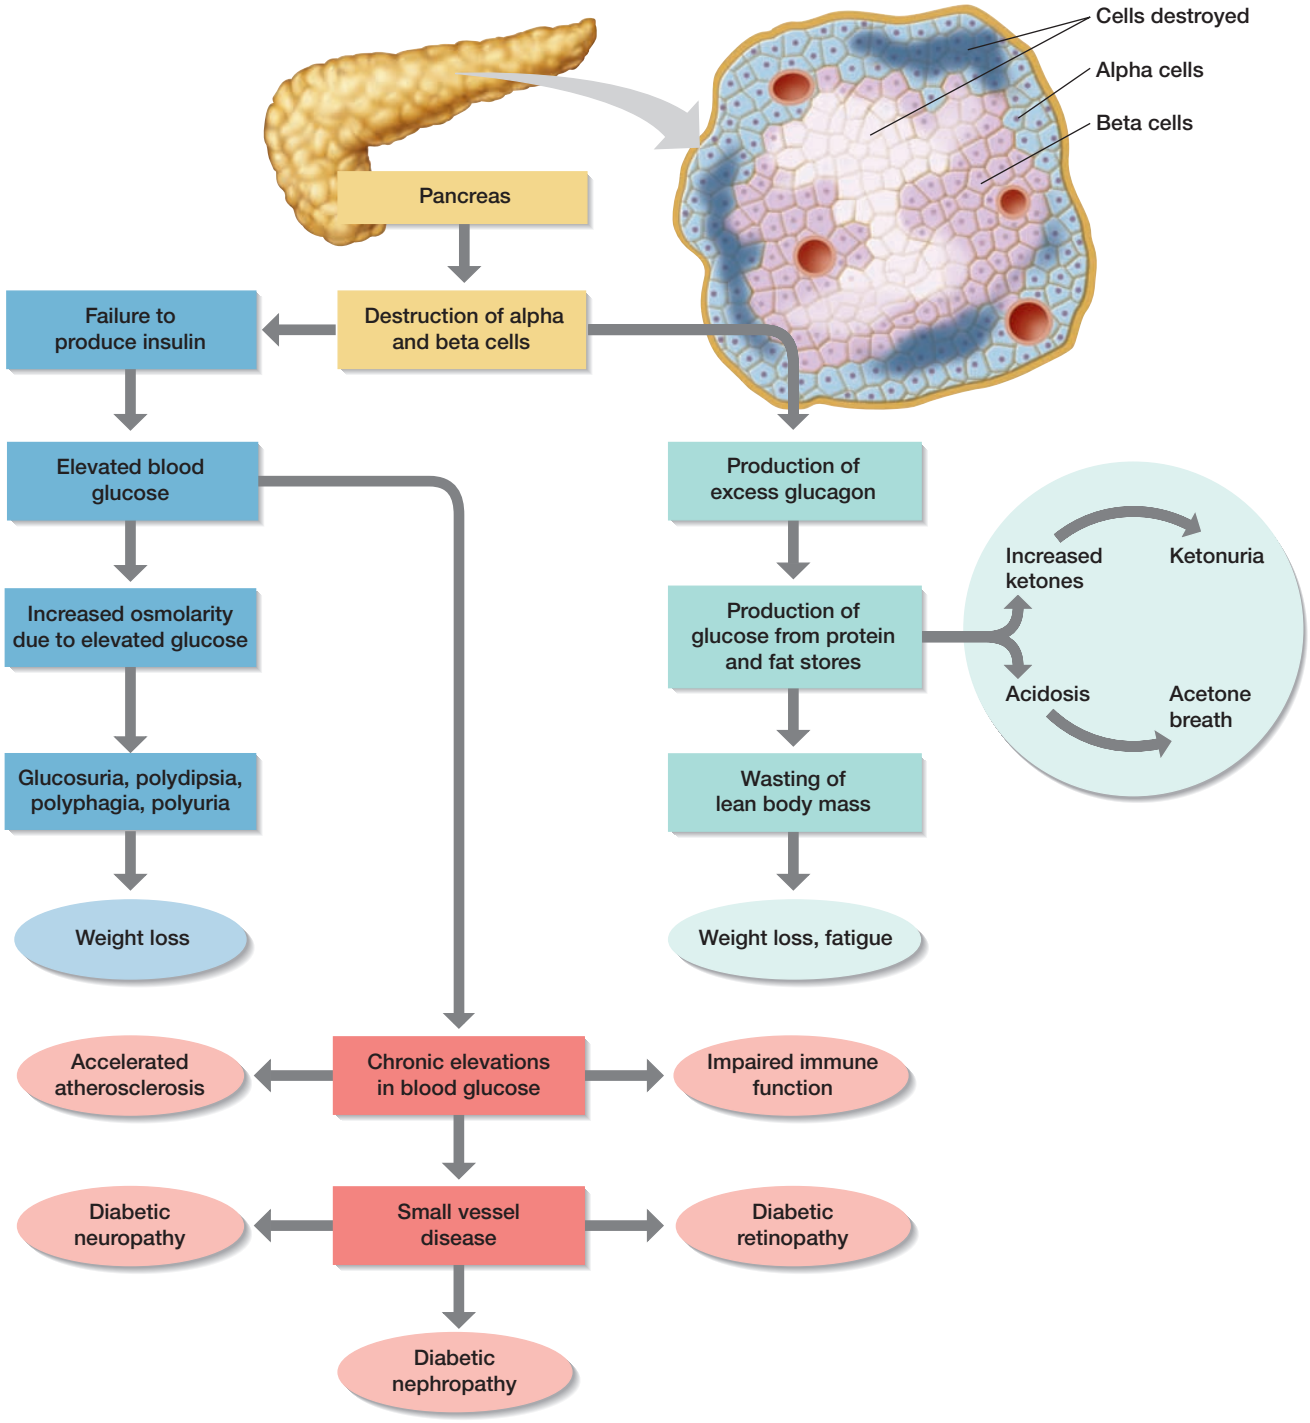
Children with type 1 diabetes generally present with polyuria, polydipsia, and weight loss. **Polyphagia** (excessive appetite) may be present. Enuresis may also occur in a previously toilet-trained child (Craig et al., 2014). The child may also present with a history of fatigue (Table 30–5). Children with new-onset diabetes may present with diabetic ketoacidosis (DKA). The prevalence varies but is higher in children less than 5 years of age with a reported incidence of 17.3% to 54.5% in that age group (Larsson et al., 2011). Other investigators report an overall incidence of DKA in youth at the time of diagnosis as being 15% to 67% (Szypowska & Skora, 2011). See the following *Clinical Tip* for information about cystic fibrosis–related diabetes.

Clinical Tip

Cystic fibrosis–related diabetes (CFRD) has similar features of types 1 and 2 diabetes; however, it is considered to be a separate condition. In cystic fibrosis, the pancreas is scarred and does not produce sufficient insulin (as in type 1 diabetes), which is referred to as **insulin deficiency**. Another mechanism of CFRD is **insulin resistance**, an impairment in insulin receptors on cell membranes, leading to inability to transfer sufficient amounts of glucose into cells, requiring higher levels of insulin for metabolism. Insulin deficiency and insulin resistance combined can lead to the development of diabetes more frequently in these patients than in the general population (Cystic Fibrosis Foundation, 2012).

Pathophysiology Illustrated: **Mechanism of Diabetes Mellitus**

Destruction of the alpha and beta cells in the islets of Langerhans produces multiple metabolic changes. Acute signs and symptoms are followed by short-term and long-term complications if the disease is not well managed.



CLINICAL THERAPY

Diagnosis is based on the presence of classic symptoms and one of the following plasma glucose levels (ADA, 2014a, p. S88; 2014b, p. S15):

- A_{1c} greater than or equal to 6.5%
- Fasting plasma glucose greater than or equal to 126 mg/dL (7 mmol/L), no caloric intake for at least 8 hours
- Two-hour plasma glucose greater than or equal to 200 mg/dL (11.1 mmol/L) during an oral glucose tolerance test
- Random plasma glucose concentration greater than or equal to 200 mg/dL (11.1 mmol/L) in a patient with classic symptoms of hyperglycemia

When an asymptomatic child's screening test reveals an elevated glucose level, confirmation of a second fasting plasma

TABLE 30–5 Clinical Manifestations of Diabetes by Type

CAUSE	CLINICAL MANIFESTATIONS	CLINICAL THERAPY
Type 1—immune mediated, insulin deficiency due to pancreatic beta-cell destruction	Polyuria, polydipsia May have polyphagia Weight loss Ketoacidosis may be present at diagnosis, at continued risk for ketoacidosis Short duration of symptoms Initial period of decreased insulin requirement, then need insulin for survival	Blood glucose monitoring Insulin Dietary management, balancing carbohydrate intake to insulin Exercise
Type 2—insulin resistance with relative insulin secretory defect	Obese, little or no weight loss, or may have significant weight loss Acanthosis nigricans Long duration of symptoms Polyuria, polydipsia, may be mild or absent Glycosuria with or without ketonuria Ketoacidosis may be present Lipid disorders Hypertension Androgen-mediated problems such as acne, hirsutism, menstrual disturbances, polycystic ovary disease Excessive weight gain and fatigue due to insulin resistance	Diet with decreased calories and low-fat foods Decrease sedentary activity time or increase routine physical activity Blood glucose monitoring Oral medication (metformin) to improve insulin sensitivity May need insulin

glucose level should be performed. An oral glucose tolerance test is rarely required. Other laboratory tests for known autoantibodies can indicate an autoimmune attack against the insulin-producing beta cells of the pancreas, and may be helpful in some cases to distinguish between types 1 and 2 diabetes. Plasma C-peptide levels are low or undetectable in type 1 diabetes, indicating little or no insulin secretion (ADA, 2014a). A careful history is necessary to rule out a stress-related illness, corticosteroid use, fracture, acute infection, cystic fibrosis, pancreatitis, or liver disease.

Clinical therapy for type 1 diabetes combines insulin, nutrition management to support growth and maintain blood glucose at near-normal levels, an exercise regimen, and psychosocial support.

Insulin Therapy. Multiple approaches to insulin therapy for children and adolescents are available, and an approach that works for the child and family should be selected. Children often need several daily injections of insulin before meals and at bedtime to maintain an optimal blood glucose level.

Clinical Tip

The American Diabetes Association (2014b) considers a fasting glucose level of 100 to 125 mg/dL (5.6 to 6.9 mmol/L) to be an *impaired fasting glucose (IFG)*, and a 2-hour postload glucose level of 140 to 199 mg/dL (7.8 to 11.0 mmol/L) to be an *impaired glucose tolerance (IGT)*. Individuals with IFG or IGT are considered at increased risk for developing diabetes. A hemoglobin A_{1c} value of 5.7% to 6.4% is an additional risk factor for the development of diabetes.

A basal-bolus insulin regimen has resulted in improved glycemic control in the pediatric population (ADA, 2014b). When multiple injections are used, basal insulin is administered once a day using a very long-acting insulin (Glargine or Detemir). A bolus of rapid-acting insulin (insulin lispro, insulin glulisine, or insulin aspart) is administered with each meal and snack based on the carbohydrate grams consumed and the blood glucose level. This means that a child may get six to seven injections a day. Stress, infection, and illness may either increase or decrease insulin needs. If basal-bolus therapy for type 1 diabetes is to be effective, the child and family need to do each of the following:

- Monitor the blood glucose appropriately to establish insulin requirements. For example, test glucose before and 2 hours after meals, as well as once a week at midnight and 3 a.m.
- Count carbohydrates consumed.
- Incorporate exercise into the daily routine.

Clinical Tip

Insulin is usually provided in prepackaged doses of 100 units/mL. Diluted insulin prepared by a pharmacist may be used for infants and toddlers who require a small insulin dosage. Insulin cartridges, disposable pens, and other devices are available, making insulin easy to carry by older children and adolescents who need frequent insulin injections during the day.

Continuous subcutaneous insulin infusion (CSII) pump therapy is being increasingly used by children and adolescents as the technology makes it possible to more closely match the plasma insulin levels found in children who do not have diabetes. CSII pump therapy has been used successfully in children of all ages and has been found to improve glycemic control with less hypoglycemia. Pump therapy requires the willingness of the patient or parent (with young children) to monitor blood glucose frequently, practice advanced insulin management skills, learn how to troubleshoot the pump, and be technology capable (Carchidi, Holland, Minnock, et al., 2011). Advantages and disadvantages of an insulin pump are outlined in Table 30–6.

Clinical Tip

Very long-acting insulins (Glargine and Detemir) cannot be mixed with other insulins.

TABLE 30–6 Advantages and Disadvantages of an External Insulin Infusion Pump

ADVANTAGES	DISADVANTAGES
• Delivers a continuous infusion of insulin to match the basal rate needed plus an insulin bolus at mealtime to more closely simulate normal pancreatic function. • Helps maintain blood glucose control between meals. • Decreases HbA_{1c} level. • Improves glycemic control. • Improves growth in children. • Reduces number of injections. • New pumps calculate bolus insulin dose to number of carbohydrates consumed. • Allows child to eat with less adherence to a schedule and have a more flexible lifestyle. • Reduces number of injection sites, so variation in absorption decreases. • Results in fewer incidences of diabetic ketoacidosis. • Improves quality of life and psychosocial functioning.	• Requires constant vigilance and adherence, including frequent blood sugar testing, carbohydrate counting, and dose calculations. • Requires willingness to live connected to a device (can be disconnected for short periods by removing or clamping the catheter; however, DKA can occur within hours of interruption of insulin flow). • Pump visibility and size. • Requires site to be changed every 2 to 3 days. • Can increase risk of infection at the injection site. • Overuse of catheter-site locations may occur. • Possible weight gain can occur when blood glucose control improves. • Costs more than other insulin therapies. • Can increase risk of DKA and ketonuria secondary to pump failure.

Tight blood glucose control has long-term benefits and is becoming a standard of care for children of all ages. Maintaining tight control for young children is challenging because of the erratic eating patterns and difficulty in recognizing symptoms of hypoglycemia (Blackman et al., 2014). In the past, target blood glucose levels were higher in younger children because of these challenges and concerns over complications of hypoglycemia. While there are still concerns, better tools are available now to detect hypoglycemia. Additionally, there is now evidence that prolonged hyperglycemia in children can lead to early development of complications such as cardiovascular and renal disease. Based on this evidence, the American Diabetes Association (2014c) now recommends a target HbA_{1c}] goal of 7.5% across all pediatric age groups. It is important however that targets for blood glucose and HbA_{1c}] be individualized to achieve the best control and minimize the risk of both hypoglycemia and hyperglycemia (Chiang, Kirkman, Laffel, et al., 2014). The HbA_{1c}] is a predictor of the average blood glucose over the past 3 months (National Diabetes Information Clearinghouse, 2014).

Complications of type 1 diabetes (retinopathy, heart disease, renal failure, and peripheral vascular disease) result from long-term hyperglycemic effects on the blood vessels. Without careful management, children with diabetes may develop renal failure and loss of vision in adulthood. Intensive therapy is expected to reduce the risk for or delay the development of these complications. Risk may be further reduced if the adolescent does not begin smoking and if the blood pressure is controlled.

Nutrition Therapy. The goal of nutrition therapy is to provide adequate calories for the child's normal growth and development. An evaluation of the child's food intake, metabolic status, and lifestyle is necessary before establishing a nutrition plan. Daily caloric requirements are individualized for each child according to need. To facilitate adherence to the nutritional plan, an individualized approach with consideration of the child's and family's culture, lifestyle, and financial means should be incorporated. Careful instruction by a registered dietician or certified nurse educator is essential in the management of diabetes.

Carbohydrate counting provides flexibility in meal planning and is simple for children and adolescents to use. One carbohydrate choice equals 15 g of carbohydrates. The number of carbohydrate choices needed at meals and snacks varies depending on the child's individualized nutrition plan. Generally, 1 unit of insulin covers 15 g of carbohydrates, making insulin dosage calculation for meal coverage relatively easy; however, a different ratio of insulin to carbohydrates may be calculated for individual children. If additional carbohydrates are eaten at a meal or snack, the number of insulin units can also be adjusted, providing further flexibility. A high-fiber diet is also recommended for improved control of blood glucose.

Exercise Program. Physical activity is associated with increased insulin sensitivity. Regular exercise and fitness improve glucose control, reduce cardiovascular risk factors, contribute to weight loss, and improve overall well-being. Blood lipid levels are also positively affected. However, the child must have an adequate caloric intake to prevent hypoglycemia. Excessive exercise associated with sports requires careful planning and management.

Nursing Management

For the Child With Type 1 Diabetes

Nursing Assessment and Diagnosis

PHYSIOLOGIC ASSESSMENT

Children with type 1 diabetes are frequently admitted to the hospital at the time of diagnosis. Assess the child's physiologic status, focusing on vital signs and level of consciousness. Assess hydration by checking mucous membranes, skin turgor, and urine output. Blood initially is collected to monitor blood gases, glucose, and electrolytes. The frequency of blood collection will depend on whether the child is in diabetic ketoacidosis. When the child is stable, assess dietary and caloric intake and the ability of the child or family to manage care.

PSYCHOSOCIAL ASSESSMENT

Parents may feel guilty at the time of diagnosis if they waited to seek care until the child began to experience symptoms of diabetic ketoacidosis. Assess coping mechanisms, family strengths and resources, ability to manage the disease, and educational

needs of both the child and parents. Examples of questions to ask in assessing the family's strengths and limitations in the child's disease management include:

- Do both parents or the single parent work? What hours?
- Who else is involved in the child's care?
- What is the child's usual daily schedule? Does the schedule vary on the weekend or any other days of the week?
- Does the child have health insurance? What coverage exists for diabetes education, treatment, and home management?
- Does the child have any cognitive, behavioral, motor, or visual problems coexisting with this condition?
- What other family stressors coexist with the diagnosis?

Clinical Reasoning **Managing Adolescent Diabetes**

Anthony, 12 years old, has just been diagnosed with diabetes mellitus. His parents took him to their family healthcare provider after Anthony complained of being constantly thirsty and hungry for over a week. Despite this, he has lost 5 lb. They note that he had a viral illness about 1 month ago but seemed to recover from it. His mother says that Anthony seemed lethargic for several days.

Anthony and his family must now learn to manage his diabetes using the combination of diet, exercise, and insulin therapy. Monitoring his blood glucose level is important in determining how much insulin he will need every day. Anthony's meals and activity will need to be coordinated with the insulin doses. Anthony and his parents will need to watch closely for signs of hypoglycemia. Develop a teaching plan that includes the following information:

- What causes diabetes?
- What potential problems need prompt treatment?
- What does Anthony need to monitor for when he gets sick?
- Intensive therapy will be a goal of Anthony's treatment. How can you help Anthony and his family decide if this should be accomplished with insulin injections or an insulin pump?
- What are some strategies to help an adolescent actively participate in his disease management and maintain optimal diabetic control?

DEVELOPMENTAL ASSESSMENT

Assess the child's developmental level, particularly fine motor skills and cognitive level. The child will need to learn how to obtain and read a blood glucose sample and how to inject insulin (see the *Clinical Skills Manual* SKILLS). Children can usually perform some of these tasks with supervision by 6 to 8 years of age.

Adolescents often perceive type 1 diabetes as a disability and may deny having the disease so they can be like their peers when eating and exercising. Talk with the adolescent and assess problem-solving skills associated with daily condition management, and the ability to manage special circumstances such as illness or changes in exercise. Self-management is the eventual goal, and the child's responsibilities are gradually increased.

Several diagnoses that may apply to the child newly diagnosed with type 1 diabetes are provided in the accompanying *Nursing Care Plans*. Additional diagnoses that may be appropriate include the following (NANDA-I © 2014):

- ***Fluid Volume: Deficient, Risk for,*** related to active fluid loss associated with hyperglycemia
- ***Breathing Pattern, Ineffective,*** related to metabolic acidosis
- ***Coping, Ineffective,*** related to inability to admit impact of disease on lifestyle

Planning and Implementation

Nursing care focuses on teaching the child and parents about the disease and its management, planning dietary intake, providing emotional support, and planning strategies for daily management in the community. Refer to the accompanying *Nursing Care Plans*, which summarize nursing care for the child who is hospitalized with newly diagnosed type 1 diabetes and the child who is receiving care in the community.

PROVIDE EDUCATION

The nurse is an important member of the management team (physician, nurse, registered dietician, certified nurse educator, and social worker) and is usually responsible for educating the child and family. The majority of teaching may be performed by an advanced practice nurse or a certified diabetes nurse educator in the clinic setting, since children may be hospitalized only briefly following diagnosis.

The timing and amount of information provided are especially important in the first days following diagnosis. Both the child and parents are very tired, and they are often in a state of shock and disbelief. Information presented during this period needs to be repeated. This time should be used to assess learning needs and to answer the family's questions. Initial teaching focuses on the survival skills necessary for home management, including insulin administration, blood glucose testing, meal planning, and the recognition and treatment of both hypoglycemia and hyperglycemia (Figure 30–6). Partner with the child and family to identify barriers to management.

Explain the goals of insulin therapy. Teach the parents and child (if appropriate) how to draw up and administer insulin or how to use an insulin pen. Insulin pens might be accepted more readily than the traditional syringe and vial method; they are

Figure 30–6 **This mother is learning how to test her child's blood glucose level.**

Nursing Care Plan: The Child Hospitalized With Newly Diagnosed Type 1 Diabetes Mellitus

1. Nursing Diagnosis: *Knowledge, Deficient (Survival Skills),* related to lack of exposure to diabetic management in the newly diagnosed child (NANDA-I © 2014)

GOAL: The child and parents will acquire survival skills for home management.

INTERVENTION	RATIONALE
• Assess the child's developmental level and select an educational approach and self-care activities to match.	• Learning goals for the child must match knowledge and skill expectations appropriate for developmental stage.
• Teach blood glucose monitoring, drawing up and injecting insulin, urine testing for ketones, record keeping, survival food guidelines, and when to call the healthcare provider.	• Diabetic management survival skills are needed for initial home management until more extensive education can be completed that permits more independent management.
• Use demonstration/return demonstration until the child and family are comfortable with procedures.	• Return demonstration permits evaluation, positive reinforcement and guidance for modification of techniques.

EXPECTED OUTCOME: Child and parents will demonstrate proper technique for blood glucose monitoring, urine testing for ketones, drawing up and injecting insulin doses, survival food guidelines, and record keeping.

GOAL: The child and parents will recognize signs and symptoms of hypoglycemia and hyperglycemia.

INTERVENTION	RATIONALE
• Teach signs and symptoms of hypoglycemic and hyperglycemic reactions.	• Recognition of and treatment of poor glucose control will prevent progression of symptoms.
• Teach the child to test blood glucose when feeling different than usual, and record the reading and symptoms felt.	• Permits child to learn his/her specific symptoms of hyperglycemia and hypoglycemia.

EXPECTED OUTCOME: Child and family will be able to describe symptoms of hypoglycemia and hyperglycemia.

2. Nursing Diagnosis: *Injury, Risk for (Complication),* related to potential episodes of hypoglycemia and diabetic ketoacidosis (NANDA-I © 2014)

GOAL: The child will experience few episodes of hypoglycemia during hospitalization.

INTERVENTION	RATIONALE
• Assess the child at least every 2 hr for signs of hypoglycemia. If signs are present, check blood glucose to verify and administer source of quick sugar.	• Hypoglycemia commonly occurs during hospitalization because of change in diet, lack of food intake, or illness.
• When the child is NPO for a special procedure, verify with healthcare provider when food, fluids, and insulin are to be given, or if an intravenous infusion with dextrose is to be given.	• Giving insulin without food intake can lead to hypoglycemia. Intravenous dextrose and insulin can be used when the child must be NPO.
• Have glucose paste or 50% dextrose solution readily available.	• Glucose paste is used for oral treatment. Dextrose is used for emergency intravenous treatment of severe hypoglycemia.

EXPECTED OUTCOME: Child and staff will manage episodes of hypoglycemia without a crisis developing.

GOAL: The child's condition will be treated slowly to gradually reverse hyperglycemia and ketoacidosis and to prevent cerebral edema.

INTERVENTION	RATIONALE
• Assess the child's mental status for improvement or deterioration.	• Improvement in mental status may indicate successful treatment. Deterioration may indicate onset of cerebral edema.

(*continued*)

Nursing Care Plan: The Child Hospitalized With Newly Diagnosed Type 1 Diabetes Mellitus (*continued*)

GOAL: The child's condition will be treated slowly to gradually reverse hyperglycemia and ketoacidosis and to prevent cerebral edema. (*continued*)

INTERVENTION	RATIONALE
• Check blood glucose and urine ketones frequently to confirm reduction in blood glucose level and ketosis, and to identify the insulin dose for administration.	• Frequent blood glucose and ketone level determination helps assess progress in treating ketoacidosis.
• Monitor and control IV fluid intake. Measure output.	• The child with ketoacidosis will be dehydrated. IV fluid intake needs to be carefully controlled to prevent cerebral edema.
• Have insulin doses checked by a second nurse.	• Doses are frequently small, and the possibility of error is great.

EXPECTED OUTCOME: Child's hyperglycemia and ketoacidosis will resolve without additional complications.

GOAL: The child and parents will demonstrate emergency management of hypoglycemia.

INTERVENTION	RATIONALE
• Identify sources of glucose to give in case of hypoglycemic reaction. Tell the child and parent to carry glucose tablets or paste with them at all times.	• Access to sources of glucose and its rapid administration are important for emergency care.

EXPECTED OUTCOME: Child and family will be able to identify several glucose sources for emergencies. The child and family have a source of glucose with them at each visit.

GOAL: The child and parents will demonstrate management of sick days.

INTERVENTION	RATIONALE
• Teach the child and family to test blood glucose and urine for ketones with acute symptoms and notify the healthcare provider.	• When the child is ill, hyperglycemia needs special management to prevent progression to ketoacidosis.

EXPECTED OUTCOME: Child's hyperglycemic episodes will not progress to ketoacidosis.

3. Nursing Diagnosis: *Nutrition, Imbalanced: Less than Body Requirements,* related to disorder of glucose and insulin (NANDA-I © 2014)

GOAL: The child will eat a well-balanced diet and maintain normal height and weight proportions.

INTERVENTION	RATIONALE
• Encourage and serve meals and snacks with consistent carbohydrates at the same time each day.	• Keeps blood glucose levels stable during initial disease management stages.
• Provide a calorie nonrestricted diet.	• Enables weight lost during onset of diabetes to be regained.

EXPECTED OUTCOME: Child will regain weight lost and demonstrate normal growth and stable blood glucose levels.

GOAL: The child and parents will state understanding of dietary management of diabetes mellitus.

INTERVENTION	RATIONALE
• Make an appointment with a registered dietician or certified nurse educator who can assess the child's favorite foods and promote their integration into the child's diet. Reinforce the dietary information taught.	• The registered dietician or certified nurse educator can develop dietary recommendations that fit the specific needs of the child and include favorite foods, thereby increasing compliance with the diet.
• Provide sample menus and teach the use of carbohydrate counting.	• Assists the family and adolescent with diet planning.

EXPECTED OUTCOME: Child and parents will describe nutritional needs of the child and select the dietary management best suited to the family's and child's eating habits.

Nursing Care Plan: The Child With Previously Diagnosed Type 1 Diabetes Being Cared for at Home

1. Nursing Diagnosis: *Nutrition, Imbalanced: Less than Body Requirements,* related to chronic illness (type 1 diabetes) (NANDA-I © 2014)

GOAL: The child will eat a well-balanced diet that maintains weight proportional to height.

INTERVENTION	RATIONALE
• Assess height and weight regularly and plot on growth chart.	• Assesses change in body mass index to identify potential weight problem early.
• Make an appointment with a registered dietician or certified nurse educator who can assess the child's favorite foods and integrate them into a food plan that controls caloric intake. Encourage the child to keep a food diary.	• Inclusion of child's favorite foods helps child adapt to changes in the food plan.

EXPECTED OUTCOME: Diet records will indicate meals and snacks have the appropriate distribution of carbohydrates, protein, and fats, and daily caloric intake goals will be met.

2. Nursing Diagnosis: *Family Processes, Readiness for Enhanced,* related to management of a chronic disease (NANDA-I © 2014)

GOAL: The child and family will manage the food plan, exercise, blood glucose monitoring, and medication regimen.

INTERVENTION	RATIONALE
• Assess the family's lifestyle and attempt to fit the child's care needs into the family's schedule.	• Fitting the care to the family's lifestyle promotes adherence with the regimen.
• Discuss the family's routines for special occasions and vacations. Identify ways to modify the child's management for these occasions.	• It is important for the child to participate in special events with the family and peers as a normal child to promote psychologic development.

EXPECTED OUTCOME: Child and family will make minimal changes in usual lifestyle while managing the type 1 diabetes.

3. Nursing Diagnosis: *Coping, Ineffective (Individual),* related to inadequate level of confidence in ability to cope (NANDA-I © 2014)

GOAL: The child will demonstrate enhanced coping skills.

INTERVENTION	RATIONALE
• Ask how the child has solved problems in the past. Review possible problems the child may encounter. Together evaluate the effectiveness of solutions. Suggest other solutions to consider.	• Children's success in mastering maturational conflicts and daily psychosocial problems will influence their pattern of coping.

EXPECTED OUTCOME: Child will demonstrate enhanced coping skills and express positive attitude toward self. Child will display warmth and affection toward family.

GOAL: The child will develop positive self-esteem.

INTERVENTION	RATIONALE
• Role-play ways to talk about diabetes with friends and teachers. Encourage the child to express feelings about diabetes to those who the child trusts.	• Sharing information about the condition helps others understand changes in lifestyle needed by the child. Expressing feelings decreases anxiety.
• Encourage the child to attend diabetes camp.	• Learning and support networks developed at camp can promote self-esteem.
• Encourage the child to continue previous social activities and hobbies.	• Increased social interaction, especially in group sessions, improves self-esteem.

EXPECTED OUTCOME: Child will demonstrate confidence in interactions with peers and maintain social network.

Families Want to Know

Checking Blood Glucose Levels

Caution parents to check the blood glucose level of a toddler who is extremely sleepy or irritable, as these can be signs of either hypoglycemia or hyperglycemia.

easier to transport, they provide more accurate dosing, and they decrease anxiety associated with needles and insulin administration in public (Hanas, de Beaufort, Hoey, et al., 2011). Rotating the injection sites is important to decrease the chances of *lipoatrophy*, loss of subcutaneous tissue, or hypertrophy in which collagen is replaced by fat cells (Figure 30–7). The absorption rate of insulin varies by the site used. Insulin is usually absorbed most rapidly from the abdomen; however, insulin absorption is increased in the extremities with exercise. An understanding of the different types of insulin and their actions is essential.

Once the child and parents demonstrate understanding of this information, teach guidelines for managing episodes of hyperglycemia during acute illness and using an insulin correction scale. A correction scale indicates specific insulin dosages appropriate for a particular blood glucose level. The family also needs to learn "sick day" care guidelines to prevent diabetic ketoacidosis.

Initial teaching related to dietary management may be taught by the registered dietician. The nurse needs to assess understanding and reinforce principles taught. Assist the parent and child (if appropriate) to learn carbohydrate counting and how to plan nutritious meals for the child. See the accompanying *Nursing Care Plans* for additional guidelines.

Eating at consistent intervals is important for glycemic control, whether counting carbohydrates or following a conventional meal plan (three meals a day and three snacks a day). Although the child with diabetes is not restricted from eating any food, the child and parents need to learn about the relationship between foods eaten and insulin needed. Meal plans also need to be adjusted for exercise. Nonnutritive sweeteners such as aspartame and saccharin may be used in moderation. The child and family should learn how to read food labels. The meal plan should be customized, with the assistance of a registered dietician to the child's age, cultural and family food preferences, and activity level.

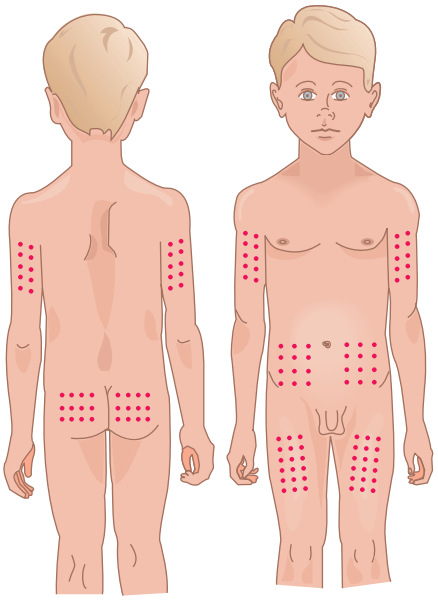

Figure 30–7 **Insulin injection sites. Give all morning insulin in one site (e.g., arms) and all evening insulin in another (e.g., legs) because of different rates of absorption from these sites. Space injections about 1.25 cm (0.5 in.) apart.**

PROVIDE EMOTIONAL SUPPORT

The diagnosis of type 1 diabetes often comes as a shock to the family. If there is a familial history, parents may feel guilty about having caused the disease. The diagnosis of a chronic disease that requires daily management can be difficult to accept. Provide the family with information about diabetes education programs, refer them to support groups with other parents of children with diabetes, and assist them in learning the role of disease management. Support for the child depends on age and developmental stage. Encourage the child to express feelings about the disease and its management. The adolescent may benefit from contact with other adolescents who have diabetes.

DISCHARGE PLANNING AND HOME CARE TEACHING

Home care needs should be identified and addressed before discharge. Initial survival skills described earlier are taught with the plans for ongoing outpatient education.

Make every effort to incorporate the diabetic regimen (insulin administration, food plan, blood glucose monitoring, and exercise) into the family's present lifestyle. The fewer changes the family has to make, the greater the chance of adherence.

The family and child newly diagnosed with diabetes should be made aware of the "honeymoon phase." This is a period during new-onset diabetes when the child has some residual beta-cell function, which reduces exogenous insulin requirements. The child and family may assume this is an indication that the diabetes "is better." However, the insulin requirement does eventually return. The duration of this phase varies among individuals.

Provide written materials and refer parents to books and other materials they can use in teaching the child about diabetes. The Juvenile Diabetes Research Foundation and the American Diabetes Association are excellent sources of information.

COMMUNITY-BASED NURSING CARE

During follow-up visits, ask the child or parents about signs indicating problems with diabetic control. Questions to ask that could help identify such problems include:

- Is the child hungry at meals? Between meals?
- How much fluid is the child drinking?
- Has the child been going to the bathroom frequently or had episodes of bed-wetting?
- Does the child have dry skin?
- Are there sores on the feet? Do scratches or scrapes take a long time to heal?
- Has the child had any skin infections?

Families Want to Know

Sick Day Guidelines

Parents should receive written guidelines specific to their child related to sick-day management. Some general guidelines include the following (American Diabetes Association, 2013; Brink et al., 2014):

- Monitor the blood glucose levels every 2 to 3 hours or as instructed.
- Test urine ketones every 4 hours or as instructed by the healthcare provider.
- The usual dose of insulin may be increased for high blood glucose levels.
- Notify the healthcare provider if the child has fever or other signs of infection, is unable to tolerate fluids, has ketones in the urine, has blood glucose levels that are out of target range, or has signs of dehydration.

- Does the child have changes in mood (depression, unexplained sadness, irritability) or energy level from day to day or throughout the day?
- Have there been any changes in vision?

Maintain a record of the child's growth measurements and vital signs. Review the child's typical dietary intake and exercise regimens. Assess the child's sexual development using Tanner staging guidelines (see Chapter 5). Puberty may be delayed if diabetic control is inadequate. Evaluation for the potential complications of diabetes should be performed annually, including blood for lipid levels, blood pressure, liver and renal function, urine for albumin, an ophthalmologic examination for retinopathy, and a neurologic examination of the extremities for neuropathies.

Education is ongoing, especially for children who develop diabetes at a young age. As they grow and assume more responsibility for their care, they need to learn more about the pathophysiology of the disease and the rationale for its management.

The child with diabetes should be treated as any other child without a chronic condition, including limit setting and consistent discipline for unacceptable behavior. Children with type 1 diabetes may learn maladaptive behaviors, using their disease to obtain something they want. Teach parents to be alert to signs of maladaption, such as helpless, demanding, or whining behaviors, and any evidence of poor coping. Additional behaviors may include skipping blood glucose testing and losing or damaging equipment. Food may become a battleground for toddlers who are picky eaters, but must eat enough for the insulin dose. Referral for counseling may be appropriate for some families.

Continually work with the child to encourage responsibility for self-care and with parents to promote the child's self-care (Figure 30–8). The child's developmental stage and cognitive level influence readiness to take on responsibility for self-care. Summer camps and other programs for children with diabetes are often helpful in providing education and support.

The preschool child's need for autonomy and control can be met by allowing the child to choose snacks or to pick which finger to stick for glucose testing and by helping parents to gather necessary supplies. School-age children can learn to test blood glucose, administer insulin, and keep records. They should be taught how to select foods and portion sizes appropriate for dietary management and how to plan food intake for an exercise program. School-age children need to learn to recognize the signs of hypoglycemia and hyperglycemia, and understand the importance of carrying a rapidly absorbed sugar product.

Although adolescents understand explanations about the potential complications of diabetes, they are present-time oriented and may rebel against the daily regimen of insulin injections, the food plan, and the exercise plan. Successful self-care depends in part on the adolescent's adjustment to the chronic nature of the disease and feelings of being different from peers. Although adolescents are able to manage self-care, the desire to be like peers may interfere with treatment adherence. Talk with adolescents to assess their mood and to evaluate their motivation to manage the meal plan, exercise regimen, blood glucose monitoring, and insulin therapy. Discuss how carbohydrate counting and insulin dose adjustment may provide the flexibility to participate in activities with peers. Collaborate with the adolescent in preparation to assume care, and assist parents in accepting the growing independence from adult supervision. A discussion of the hazards associated with having diabetes and the use of alcohol, drugs, and tobacco should occur. At every subsequent healthcare visit, the adolescent should be asked about alcohol intake. See *Evidence-Based Practice: Coping With Type 1 Diabetes in Adolescents*.

Figure 30–8 **This girl is old enough to understand the need to take glucose tablets or another form of a rapidly absorbed sugar when her blood glucose level is low.**

EVIDENCE-BASED PRACTICE | Coping With Type 1 Diabetes in Adolescents

Clinical Question

What factors are associated with how adolescents cope with type 1 diabetes?

The Evidence

Jaser and White (2011) explored how coping strategies affect resilience in adolescents with type 1 diabetes. Thirty participants ages 10 to 16 years with type 1 diabetes and their mothers completed questionnaires that focused on the teens' use of coping strategies, competence, and quality of life. Hemoglobin A_{1c} measurements were obtained from each teen's medical record. The study examined how adolescents use primary control and secondary control engagement strategies and/or disengagement strategies to cope with stress related to diabetes. Primary control coping strategies such as problem solving and emotional expression and secondary control coping strategies such as acceptance and distraction were associated with better metabolic control, better quality of life, and higher social competence. Use of disengagement strategies such as withdrawal or denial were associated with poorer metabolic control and lower social competence.

Jaser et al. (2012) studied the relationship of coping and stress reactivity with metabolic control, quality of life, and self-management in adolescents with type 1 diabetes. An ethnically diverse sample of 327 adolescents ages 11 to 14 with type 1 diabetes completed questionnaires about coping and stress reactivity, self-management, and quality of life. Hemoglobin A_{1c} measurements were obtained from medical records. Participants from low-income families and minority status had lower levels of primary control coping such as problem solving and secondary control coping such as acceptance. This group also had higher levels of disengagement coping such as avoidance. Results of the study also revealed that the use of primary and secondary control strategies to cope with stress related to diabetes was correlated with better self-management and better adaptation. The investigators concluded that there are differences in coping related to income and ethnicity and that coping strategies impact self-management and metabolic control in adolescents with diabetes.

Iafusco et al. (2011) evaluated the effectiveness of a chat line for adolescents with type 1 diabetes on quality of life and metabolic control. The participants were 193 children and adolescents 10 to 18 years of age. Computer-based chats, moderated by a physician, took place once a week and covered topics such as diabetes management, fears related to hypoglycemia, anxiety related to the future, and relationships. At routine office visits, a research assistant gathered demographic data and assessed management of diabetes. Questionnaires, including the Diabetes Quality of Life for Youth Inventory (DQOLY), were completed at baseline, 1, and 2 years. A control group consisted of 203 adolescents who did not participate in the chat line. Results of the study found that participation at least once a month in the chat group improved well-being and metabolic control.

Best Practice

Adolescents with type 1 diabetes must cope with the increasing responsibility for complex self-management, including insulin administration, blood glucose testing, exercise, and nutrition. The types of coping strategies that are used affect the adolescent's quality of life and metabolic control. It is important that these adolescents learn effective coping strategies such as problem solving and distraction. Interventions that involve group discussions about concerns related to diabetes and routine follow-up to assess coping strategies, quality of life, and metabolic control are essential in maximizing outcomes for these adolescents with diabetes.

Clinical Reasoning

How can you address coping strategies and quality of life issues in adolescents with diabetes? What interventions can you think of that may improve quality of life and metabolic control in these adolescents?

The child with type 1 diabetes may develop circulatory and neurologic changes over time. Emphasize the importance of good foot care from an early age—for example, wearing clean cotton socks, changing socks and shoes when they are damp, washing and drying feet, and keeping toenails short. Adolescents getting pedicures should inform the person performing them that they have diabetes.

Explain to parents that the child should wear some type of medical alert identification. Help them have an individualized school health plan developed (see Chapter 12) to ensure that school administrators and teachers can identify the signs of hypoglycemia or hyperglycemia and provide emergency management.

Evaluation

Expected outcomes of nursing care for children with type 1 diabetes can be found in the *Nursing Care Plans* in this chapter.

Diabetic Ketoacidosis

Diabetic ketoacidosis (DKA) is a common and potentially life-threatening condition that occurs primarily in children with type 1 diabetes. Potential causes of DKA include incorrect or missed insulin doses, incorrect administration of insulin, or an illness, trauma, or surgery. DKA may be present in children with new-onset diabetes.

Professionalism in Practice Management of Diabetes in the School Setting

Section 504 of the Rehabilitation Act of 1973 and the Americans with Disabilities Act of 1990 are federal laws that require that students with disabilities, including those with diabetes, be given an equal opportunity to participate in school activities. The position statement of the National Association of School Nurses states that a school nurse is required to develop an individualized health plan from the child's diabetes medical management plan. The school nurse oversees the implementation and evaluation of the plan (Butler, Fekaris, Pontius, et al., 2012). It is essential for the school nurse to work with parents to ensure that equipment and medications needed at school are provided so that children with disabilities are able to receive the care they need.

Health Promotion The Child With Diabetes Mellitus

Growth and Development Surveillance

- Compare the child's height, weight, and head circumference to age-specific norms to determine if growth is meeting expectations for age. Monitor body mass index (BMI) percentile at each healthcare visit.
- Assess developmental progress using the Denver II or another screening tool (refer to Chapter 6). Assess school performance.
- Assess for delays in development of secondary sexual characteristics and pubertal changes.

Nutrition

- Promote adherence to nutrition guidelines by including the child's personal preferences in the food plan.

Physical Activity

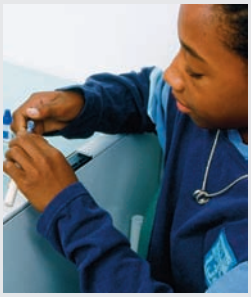
- Encourage regular physical activity and educate the child to modify insulin dosage or food intake for extra physical activity periods.
- Encourage the child to participate in sports when interested and work to balance exercise, food intake, and insulin dosage.

Oral Health

- Promote good dentition and oral hygiene.
- Regular dental visits are important to reduce risk of infections.
- The child with poorly controlled diabetes is at risk of gingivitis and cavities.

Mental and Spiritual Health

- Provide the child and adolescent an opportunity to discuss feelings regarding diabetes.
- Assess the adolescent for evidence of depression.



Relationships

- The child should attend school or child care as any other child. Parents may need support to find facilities able to monitor the child as needed and to provide the teaching required for facility employees.
- Encourage the development of special friends who can be informed about the child's disorder and seek help when the child has signs of hypoglycemia or hyperglycemia.

Disease Prevention Strategies

- Encourage the family to ensure that the child receives all recommended immunizations, including an annual influenza vaccine.
- Refer the child for an annual ophthalmologic examination.
- Maintain appointments for regular evaluation of HbA_{1c} to monitor glycemic control.

Injury Prevention Strategies

- Encourage the child to wear a medical alert identification.
- Encourage daily inspection of feet and foot care.
- Provide the family with strategies for safe disposal of needles and syringes.

Insulin deficiency is accompanied by a compensatory increase in hormones (epinephrine, norepinephrine, cortisol, growth hormone, and glucagon) that are released when inadequate glucose is delivered to the cells. The muscle cells break down protein into amino acids that are then converted to glucose by the liver, leading to hyperglycemia. The adipose tissue releases fatty acids that are transformed by the liver into ketone bodies. Their accumulation leads to ketoacidosis. The hyperglycemia causes an osmotic diuresis resulting in dehydration, acidosis, and hyperosmolality. The rising ketones lead to metabolic acidosis. DKA is associated with severe metabolic, electrolyte, and fluid imbalances.

Characteristic signs of DKA include polyuria, polydipsia, weight loss, abdominal pain, nausea and vomiting, tachycardia, signs of dehydration, flushed ears and cheeks, Kussmaul respirations, acetone breath (fruity smell), altered level of consciousness, and hypotension. Hyperglycemia, glycosuria, and ketonuria are also present. In response to metabolic acidosis, children complain of abdominal or chest pain, nausea, and vomiting. The disorder may progress to electrolyte disturbances, arrhythmias, altered consciousness, pupillary changes, irregular respirations, inappropriate slowing of the heart rate, and widening pulse pressure. See Table 30–7 for clinical manifestations of hypoglycemia and hyperglycemia.

Diabetic ketoacidosis is present with the following findings: blood glucose level greater than 250 mg/dL, serum ketones, acidosis (pH less than 7.3 and bicarbonate less than 15 mEq/L), and ketonuria. Alteration in electrolytes occur. The blood urea nitrogen (BUN) and creatinine are elevated (Masharani, 2015).

The child with ketoacidosis is hospitalized. Medical management includes isotonic intravenous fluids and electrolytes for dehydration and acidosis. Intravenous insulin (0.1 unit/kg per hour) is administered by continuous infusion pump to decrease the serum glucose level at a rate not to exceed 100 mg/dL/hr. Faster reduction of hyperglycemia and serum osmolality increases the risk for cerebral edema. When glucose is lowered too rapidly, water is freed and attracted to the glucose, which has accumulated in large quantities in the brain. Cerebral edema is the most common complication of DKA and the most common cause of death in children with diabetes (Bialo, Agrawal, Boney, et al., 2015). As insulin and fluids are administered, potassium shifts to the cells, resulting in hypokalemia. Potassium replacement is needed as hypokalemia can lead to cardiac arrhythmia (McFarlane, 2011). See Chapter 27 for information about cerebral edema.

Nursing Management

Continuously monitor the child's vital signs, respiratory status, perfusion, and mental status. Assess for changes in neurologic status, respiratory pattern, blood pressure, and heart rate. Monitor for cardiac arrhythmias associated with hypokalemia. Assess for signs of dehydration, including dry skin and mucous membranes and depressed fontanelles in infants. Monitor blood glucose levels

hourly or as indicated. Frequently monitor the electrolytes and acid–base status, as well as urine glucose and ketone levels as indicated. Intake and output are monitored hourly. Assess for signs of hypoglycemia that may occur during insulin infusion.

Intravenous fluids are given in boluses of 10 to 20 mL/kg rapidly over 5 minutes if the child is in hypovolemic shock. Adequate fluids are given to reverse the fluid deficit. The insulin infusion must be carefully titrated to control the gradual reduction in hyperglycemia. The child is tapered off intravenous insulin and transitioned to subcutaneous insulin when clinically stable. Oral feedings are reintroduced when the child is alert and the glucose level is stabilized.

The prevention of future episodes of DKA is important. The parents and child need to learn strategies to keep hyperglycemic episodes from progressing to DKA. Parents should have specific instructions on how often to check the blood glucose and when to check the urine for ketones when the child is sick. If the child has an elevated blood glucose and moderate or large amounts of ketones, treatment with extra insulin and fluids can be initiated. Increased attention to blood glucose and urine ketone monitoring is especially important when the child has significant stressors such as an illness. It is important for the child and family to understand that insulin is required even when the child is not eating to counter the hormones secreted in response to the stressor.

SAFETY ALERT!

Only regular insulin is administered intravenously for treatment of hyperglycemia or diabetic ketoacidosis. Do not use other insulin types as they may lower the blood glucose too rapidly or too slowly.

Hypoglycemia in the Child With Diabetes

Hypoglycemia can develop within minutes in children with type 1 diabetes mellitus. The symptoms outlined in Table 30–7 may occur when blood glucose levels suddenly drop or fall below 70 mg/dL. Children are at risk of hypoglycemia because of their rapid growth rates and unpredictable eating habits and physical activity.

Families Want to Know

Preventing DKA

When to Monitor for DKA

- Abdominal pain
- Nausea, vomiting, and anorexia
- 1- or 2-day history of polyuria and polydipsia
- Has illness (e.g., viral or other) and is unable to eat

Recognizing Signs of DKA

- Change in mental status
- Blood glucose greater than 250 mg/dL
- Moderate to large ketones present in urine
- Fruity breath odor
- Rapid, deep respirations
- Decreased urine output

New York, NY: McGraw-Hill; McFarlane, K. (2011). An overview of diabetic ketoacidosis in children. *Paediatric Nursing, 23*(1), 14–19.

Families Want to Know

Treating Hypoglycemic Episodes

- If the child shows signs of hypoglycemia (pallor, sweating, tremors, dizziness, numb lips or mouth, confusion, irritability, altered mental status), test the blood glucose level.
- Assist the child to perform the test. Skills needed to get an accurate reading deteriorate with altered mental status.
- If the blood glucose reading is less than or equal to 70 mg/dL, give glucose rapidly. Use one of the following to give 15 g of rapid-acting glucose to raise the blood sugar level:
  - $\frac{1}{2}$ cup fruit juice
  - $\frac{1}{2}$ cup of regular cola or soda
  - 1 small box raisins
  - 3 to 4 glucose tablets
- Wait 15 minutes and recheck the blood glucose level. Repeat the 15 g of rapid-acting glucose if it is still less than or equal to 70 mg/dL. Recheck the blood glucose level in another 15 minutes.
- When blood sugar has returned to at least 80 mg/dL, give a more substantial snack such as cheese and crackers if the next meal will be more than 30 minutes later or an activity or exercise is planned.
- If the child is unconscious, administer glucagon by injection or spread glucose paste on the gums.

TABLE 30–7 Clinical Manifestations of Hypoglycemia and Hyperglycemia

CAUSE	CLINICAL MANIFESTATIONS	CLINICAL THERAPY
HYPOGLYCEMIA		
• Insulin dose too high for food eaten • Insulin injection into muscle • Too much exercise for insulin dose • Too long between meals/snacks • Too few carbohydrates eaten • Illness, stress	Rapid onset Irritability, nervousness, tremors, shaky feeling, difficulty concentrating or speaking, behavior change, confusion, repeating something over and over Unconsciousness, seizure, shallow breathing, tachycardia Pallor, sweating Moist mucous membranes, hunger Headache, dizziness, blurred vision, double vision, photophobia Numb lips or mouth	If conscious, give 15 g of carbohydrate. Wait 15 minutes and recheck blood glucose level. Give another 15 g of carbohydrate if 70 mg/dL or below. Recheck the blood glucose level in 15 minutes. If unconscious, give glucagon by injection.
HYPERGLYCEMIA		
• Insulin dose too low for food eaten • Illness or injury, stress • Too many carbohydrates eaten • Meals/snacks too close together • Insulin injected just under skin or injected into hypertrophied areas • Decreased activity	Gradual onset Lethargy, sleepiness, slowed responses, or confusion Deep, rapid breathing Flushed skin, dry skin Dry mucous membranes, thirst, hunger, dehydration Weakness, fatigue Headache, abdominal pain, nausea, vomiting Blurred vision Shock	Give additional insulin at usual injection time. Give correction scale insulin doses for specific blood glucose levels when ill or injured. Give extra injections if hyperglycemia and moderate to large ketones. Increase fluids.

Severe hypoglycemic episodes may occur at night in children who are treated with two to three injections per day. Other common causes include an error in insulin dosage, errors in injection technique, inadequate calories because of missed meals, or exercise without a corresponding increase in caloric intake. Severe hypoglycemia can cause seizures.

Hypoglycemia can be diagnosed on the basis of the sudden onset of signs and symptoms. A blood glucose reading should be taken to confirm a low blood sugar is possible if equipment is readily available. Give a glucose source immediately by mouth. If the child becomes unconscious, administer an injection of glucagon, or, if unavailable, administer sugar gel or glucose paste squeezed onto the gums. In the hospital setting, administer an intravenous infusion of dextrose to prevent progression of symptoms. Since the effects of dextrose and glucagon are temporary, additional snacks or a meal is provided. The child should be continually observed for several hours after treatment.

Nursing Management

Teach parents and children to recognize the signs of hypoglycemia and take appropriate action. Parents are taught to give **glucagon** (a hormone produced by the pancreas that helps release stored glucose from the liver) by injection for cases of severe hypoglycemia and to activate the emergency medical system (9-1-1). Reinforce the importance of balancing dietary intake, insulin, and exercise every day.

Type 2 Diabetes

Type 2 diabetes is a disease associated with insulin resistance (an alteration of the insulin receptor that signals the presence of insulin in the interior of cells). Significant risk factors for type 2 diabetes includes obesity, low levels of physical activity, intake of high-energy foods, low socioeconomic status, ethnicity, and family history of diabetes (Bacon, 2013; Dea, 2011; Svoren & Jospe, 2016). Over 75% of children with type 2 diabetes have a first- or second-degree relative with diabetes (Dea, 2011).

The increasing number of children being diagnosed with type 2 diabetes has caused significant concern in the healthcare community. According to the SEARCH for Diabetes in Youth Study, an estimated 5089 people younger than 20 years were newly diagnosed with type 2 diabetes annually during 2008 to 2009. The incidence was highest in children ages 10 to 19 and in U.S. minority populations (CDC, 2014). The true incidence is unknown because many children are undiagnosed.

Developing Cultural Competence Type 2 Diabetes Risk

Children of African American, Native American, Hispanic/Latino, and Asian/Pacific Islander origins are at greater risk for developing type 2 diabetes (American Diabetes Association, 2015).

ETIOLOGY AND PATHOPHYSIOLOGY

Children who are obese are at risk to develop type 2 diabetes because the excess body fat decreases the body's ability to use insulin (Bacon, 2013). The onset of puberty and increased secretion of growth hormone are believed to be contributing factors in the development of insulin resistance (Dea, 2011). The pancreatic cells produce more insulin in an attempt to overcome the insulin resistance and maintain a normal glucose tolerance. When the

beta cells are not able to produce enough insulin, blood glucose levels increase (Khan, Cooper, & Del Prato, 2014).

CLINICAL MANIFESTATIONS

Signs and symptoms of type 2 diabetes vary. The child may not have any symptoms or may present with polydipsia, polyuria, blurred vision, and fatigue (American Diabetes Association, 2015). **Acanthosis nigricans** is described as a hyperpigmentation and thickening of the skin with velvety irregularities in the skin folds of the back of the neck, axillae, and flexor skin surfaces. It has been established as a risk factor for the development of type 2 diabetes and is associated with insulin resistance (Abraham & Rozmus, 2012) (see Figure 30–9). The child with type 2 diabetes is usually obese with a high waist circumference. Approximately 5% to 25% of children with type 2 diabetes present with ketoacidosis at the time of diagnosis (Dea, 2011).

CLINICAL THERAPY

Blood glucose levels of 200 mg/dL or greater without fasting or a fasting glucose of 126 mg/dL or greater, are diagnostic of diabetes (ADA, 2014b). HbA_{1c}] predicts the average blood glucose over the past 3 months (National Diabetes Information Clearinghouse, 2014). Islet cell autoantibodies, fasting insulin levels, and C-peptide levels are used to help differentiate between type 1 and type 2 diabetes but are not definitive. Islet cell autoantibodies (GAD-65, islet cell antibodies, insulin) are suggestive for type 1 diabetes; however, autoantibodies specific to a certain antigen are not present in approximately 15% of children with type 1 diabetes. Additionally, some children with type 2 diabetes will have detectable autoantibodies. While insulin and C-peptide levels are usually low in children with type 1 diabetes, there is some overlap with type 2, so these values are not helpful with the initial classification (Cohee, 2012). A fasting lipid profile is obtained since dyslipidemia (primarily elevated triglycerides and LDL cholesterol) is usually present (Svoren & Jospe, 2016). High blood pressure for age, gender, and height percentile is also seen (see Appendix B).

The multiple goals for managing the child with type 2 diabetes include the following: normalizing the blood glucose and HbA_{1c} levels, decreasing weight, increasing exercise, normalizing lipid profile and blood pressure, and preventing complications. Nutrition education and weight loss make up the major therapy.

Figure 30–9 **Acanthosis nigricans.**

SOURCE: Benedicte Desrus/Alamy.

The child needs to have gradual, sustained weight loss, metabolic control of blood glucose levels, exercise, and emotional support.

If the child or adolescent presents with severe hyperglycemia or diabetic ketoacidosis, insulin will be required to gain initial glycemic control. When metabolic control is achieved, oral medication (metformin) is initiated as the child is weaned off of insulin. Metformin is used when diet and exercise efforts are inadequate to control hyperglycemia. Metformin improves the sensitivity of target cells to insulin, slows the gastrointestinal absorption of glucose, and reduces hepatic and renal glucose production. It can be used when there is normal liver and kidney function and no ketosis. The dosage may be gradually increased to improve metabolic control. If additional medication is needed, sulfonylureas may be used if metformin alone is not adequate or is contraindicated, but their use in pediatrics is limited. Thiazolidinediones are not approved for use in children but may be used if metformin is contraindicated. Some children ultimately require insulin for glycemic control (Svoren & Jospe, 2016).

Nursing Management

For the Child With Type 2 Diabetes

Nursing Assessment and Diagnosis

Because the child with type 2 diabetes does not often have an acute onset, assess any child with a body mass index (BMI) greater than 85th percentile for age and gender for signs of insulin resistance (acanthosis nigricans, hypertension, and dyslipidemia). Family history of diabetes in an overweight child is a reason to begin screening for the condition. Once the child has been diagnosed, monitor the child's blood glucose levels and blood pressure. Assess the child's diet and activity patterns to determine appropriate changes for disease management. Consider evaluating the siblings for diabetes.

Nursing diagnoses that may apply to the child with type 2 diabetes include the following (NANDA-I © 2014):

- ***Activity Intolerance*** related to sedentary lifestyle and disease state (insulin resistance)
- ***Health Management, Family, Ineffective,*** related to family conflict over changing eating patterns
- ***Self-Esteem, Situational Low,*** related to situational crisis associated with diagnosis of new-onset chronic illness

Planning and Implementation

The child with type 2 diabetes may be hospitalized at the time of diagnosis because of ketoacidosis. However, the nurse in an inpatient setting is more likely to encounter this child when hospitalized for another condition or during visits for health care in clinics or schools. Nursing care focuses on managing the child's blood glucose levels and hypertension during the hospitalization, assessing growth and dietary intake, evaluating goals for weight loss and exercise programs, and reviewing the child's knowledge about diabetes and strategies for management at home.

COMMUNITY-BASED NURSING CARE

Since the child is initially diagnosed with type 2 diabetes and managed on an outpatient basis, nursing care focuses on teaching the child and parents about the disease and its management, managing dietary intake, providing emotional support, and planning strategies for daily management in the community.

Educate the child and family about the disease and lifestyle changes required for effective management of the condition. Focus on the need to increase activity with routine exercise of

at least 30 to 60 minutes daily and to decrease sedentary activity time, such as computer and television viewing time to no more than 2 hours daily. Customize the activity strategy for each child with motivation to develop a regular routine.

Work with the family to substitute high-calorie and high-fat foods with a meal plan sensitive to the family's resources and ethnic preferences. Suggestions include limiting fast food and snacking on fruits and vegetables rather than foods high in fat and sugar. Assess the child's height, weight, and BMI on each visit, and plot on the appropriate growth curve for age and gender. A gradual sustained weight loss or decrease in BMI is the goal. If the child is experiencing a height growth spurt, maintenance of weight rather than weight loss is the goal. Encourage the entire family to make dietary changes, especially since other family members are also at risk for the condition.

Teach the child and family to perform home blood glucose testing to monitor glycemic control. This will let the child and family know that efforts to manage the disease are successful. Take HbA_{1c} levels at each visit to determine the average blood glucose level for the past 3 months. When dietary control and exercise are not successful in reducing blood glucose levels, teach the child and family about the prescribed oral medication.

Give the child and family opportunities to talk about the impact of the disease on their lives. Identify resources for information about strategies that have worked for other families. Identify local support groups and peer groups for the family and child. Suggest weekly activities, summer camps, and other ongoing programs to provide necessary support and motivation.

Make sure the child gets annual evaluations for potential complications of diabetes. The tests to be performed include blood for lipid levels, blood pressure, liver and renal function, urine for albumin, an eye examination for retinopathy, and a neurologic examination of the extremities for neuropathies. The child with type 2 diabetes has the same risk for developing long-term vascular complications as the child with type 1 diabetes when hyperglycemia is poorly controlled.

Evaluation

Examples of expected outcomes of nursing care include the following:

- The child decreases sedentary activity time to less than 2 hours a day.
- The child's daily intake of fruits and vegetables increases to five to eight servings daily, and total fat intake decreases to less than 30% of total calories.
- The child's BMI slowly and consistently decreases.

Disorders of Gonadal Function

Gynecomastia

Gynecomastia is a proliferation of glandular breast tissue in males that occurs in approximately 40% to 65% of adolescent boys. Gynecomastia results from an imbalance in estrogens and androgens in the breast tissue. Gynecomastia is generally idiopathic, although it can be associated with a chronic disorders, tumors, or drug use (Saito et al., 2014). The condition disappears in 75% of cases. If gynecomastia is causing pain or psychologic distress to the adolescent, treatment with a medication such as tamoxifen or surgical intervention with a minimally invasive approach may be indicated (Fischer et al., 2014).

Nursing care focuses on reassuring the child and his parents that gynecomastia is common and transient. Because of the body image concerns common during adolescence, embarrassment is a frequent problem. Recommend clothing styles and other methods to camouflage the enlarged breasts. If treatment is indicated, education regarding medication use or surgery is needed.

Amenorrhea

Amenorrhea, or lack of menstruation, may be primary or secondary. Criteria for primary amenorrhea include absence of menarche by age 14.5 years in association with no growth or development of secondary sexual characteristics, or absence of menses by age 16 when secondary sexual characteristics and growth are present.

Secondary amenorrhea is the cessation of menstrual periods 6 months or 3 cycles after menstruation has begun; it is characterized by an absence of spontaneous bleeding for at least 120 days. Pregnancy is the most common cause of secondary amenorrhea in adolescents. It is common for adolescents to have irregular menstrual cycles and duration of the menstrual period for 1 to 2 years after menarche. A large number of cycles are anovulatory for the first 2 years after menarche.

Primary amenorrhea is most often caused by structural defects of the reproductive system; chromosomal abnormalities (such as Turner syndrome); hypothalamic or pituitary tumors; thyroid dysfunction; or polycystic ovary syndrome. No underlying pathologic condition is found in some adolescents. Primary or secondary amenorrhea may be found in competitive athletes and in youth with anorexia nervosa (see Chapter 14).

A thorough history (including sexual activity), physical examination, and laboratory evaluation are required to determine the cause of amenorrhea. The history focuses on asking questions about recent excessive weight loss or gain; excessive physical activity or sports training; chronic illness; use of illegal drugs, birth control pills, or phenothiazines; emotional problems; and age of the mother at menarche. A family history helps to identify other female family members with similar issues. The physical examination focuses on evaluating the adolescent's stage of sexual development and assessing for hirsutism (see Chapter 5). A vaginal exam is performed to determine vaginal patency and if the vaginal mucosa is estrogenized. A pregnancy test is performed. Bone age and hormone levels are evaluated (estrogen, LH, FSH, and prolactin).

Growth and Development

Girls competing in sports such as long-distance running and track and field may be at increased risk for musculoskeletal injury. The female athlete triad places the runner at increased risk for injury such as stress fractures and comprises these three components: low energy availability (with or without disordered eating), low bone mineral density, and menstrual dysfunction. Research indicates that oligomenorrhea (infrequent menstruation) or amenorrhea (lack of menstruation) and low bone mineral density are associated with injury in the lower extremities (Rauh, Barrack, & Nichols, 2014) (see Chapter 29).

Treatment of amenorrhea depends on the specific cause. The most common approach is to prescribe birth control pills containing both estrogen and progesterone. Athletic teenagers are encouraged to eat a well-balanced, high-calorie diet. Calcium supplements may be ordered. Estrogen with progesterone in low doses may be prescribed for athletes to reduce the risk for osteoporosis. Nursing management centers on patient education and emotional support. The goal is to maintain normal growth and development.

Dysmenorrhea

Dysmenorrhea (menstrual pain or cramping) is a common problem in adolescent females. Primary dysmenorrhea refers to painful menstrual cramps that occur without any underlying disease process and affects 80% to 90% of female adolescents and women who are menstruating (Maruf, Ezenwafor, Moroof, et al., 2013). Primary dysmenorrhea is usually caused by an increased secretion of prostaglandins that are produced during the ovulatory cycle. Prostaglandin causes smooth muscle contraction in the uterus, leading to pain (Calis, Erogul, Popat, et al., 2015). Dysmenorrhea is the leading cause of school absence in the female adolescent population (Maruf et al., 2013; Wong, Ip, Choi, et al., 2015).

Dysmenorrhea usually occurs just prior to or at the beginning of the menstrual period and decreases over 1 to 3 days. The cramping pain ranges from mild to severe and varies with the individual. Other symptoms may include dizziness, syncope, nausea, vomiting, diarrhea, headache, lightheadedness, and fatigue (Maruf et al., 2013).

The treatment of choice for primary dysmenorrhea is nonsteroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen and naproxen sodium. These drugs inhibit prostaglandin synthesis, which leads to a reduction in uterine activity and pain. Oral contraceptives may be prescribed to prevent ovulation and to decrease prostaglandin production. A gynecologic examination may be conducted to rule out any structural abnormalities.

Secondary dysmenorrhea is defined as painful menstruation associated with pelvic abnormalities. Common causes of secondary dysmenorrhea include endometriosis, uterine fibroids, pelvic inflammatory disease, tubo-ovarian abscess, ovarian torsion, ovarian cyst, and presence of an intrauterine device (Calis et al., 2015). Vaginal and cervical cultures are taken when a sexually transmitted infection is possible. See Chapter 26.

Nursing Management

Nursing care centers on providing patient education and emotional support. Instruct the adolescent with chronic dysmenorrhea to keep a calendar and begin taking NSAIDs 1 day before the onset of the menstrual period. The medications should be taken with food to minimize side effects.

Disorders Related to Sex Chromosome Abnormalities

Turner Syndrome

In Turner syndrome, girls have a missing or partial absence of one X chromosome. This condition occurs in approximately 1 in 2000 to 1 in 5000 live female births (Oliveira, Ribeiro, Lago, et al., 2013). An estimated 90% of fetuses with Turner syndrome are spontaneously aborted during the first trimester. Turner syndrome is primarily associated with short stature and infertility (Martin & Smyth, 2012).

Characteristic clinical findings in the newborn include edema of the hands and feet, a webbed neck, a low hairline, a high-arched palate, a small jaw, low-set ears, droopy eyelids, a short fourth toe, short fingers, a broad chest, and widely separated nipples (Figure 30–10). Some children may have only one or two mild symptoms, and the diagnosis may not be made until adolescence when pubertal delay and lack of the onset of menstruation are apparent (Martin & Smyth, 2012).

Growth usually proceeds at a normal rate until around 3 years of life and then slows, ceasing after puberty (Walker, 2014).

Figure 30–10 What characteristic physical manifestations of Turner syndrome can you identify in this girl?

SOURCE: Ed Suba Jr./Akron Beacon Journal/AP Photo.

Congenital heart defects frequently associated with Turner syndrome include coarctation of the aorta and bicuspid aortic valve (Levitsky, Luria, Hayes, et al., 2015). Other associated conditions include hearing loss, structural abnormalities of the kidney, and ophthalmic abnormalities (Martin & Smyth, 2012). Musculoskeletal disorders may include scoliosis and osteoporosis (Walker, 2014).

Diagnosis of Turner syndrome may be determined prenatally by amniocentesis or chorionic villi sampling (Martin & Smyth, 2012). The condition is diagnosed definitively by a karyotype. The most common phenotype is 45,X, indicating an absent X chromosome, which occurs in 40% to 60% of girls with Turner syndrome (Oliveira et al., 2013). Other types of Turner syndrome occur when the X chromosome is partially missing or rearranged, or when there are chromosomal changes in some of the cells (mosaicism) (Genetics Home Reference, 2012).

Treatment involves careful monitoring of the child's growth. A growth chart made especially for girls with Turner syndrome is available from the Turner Syndrome Society. Growth hormone therapy may be prescribed to promote growth during childhood. With treatment, final height generally reaches approximately 5 feet 2 inches; without treatment, the final height is approximately 4 feet 8 inches (Martin & Smyth, 2012). Estrogen and progesterone therapy are generally prescribed to promote breast development and decrease the risk of osteoporosis (Walker, 2014).

Nursing Management

Nursing assessment is focused on monitoring growth rates and observing for signs of cardiac, renal, gastrointestinal, vision, hearing, musculoskeletal, or thyroid dysfunction. Carefully measure the child's height and plot on the growth curve. Teach the family the correct administration of growth hormone and potential side effects.

The lack of growth and sexual development associated with Turner syndrome presents problems not only for physical growth but also for psychosocial development. The girl's perception of her body and how she differs from peers affects self-image, self-consciousness, and self-esteem. In the United States, cultural values place importance on attaining normal to tall stature. Short children tend to be treated according to their size rather than their age. Emphasis is also placed on sexual maturity. Encourage parents to treat the child by her chronologic age rather than size. Even though the child's intelligence is generally normal, learning disabilities are common (Saenz, Tsai, Manchester, et. al., 2014).

Klinefelter Syndrome

Klinefelter syndrome is a genetic condition that occurs in boys who have an extra X chromosome (usually 47,XXY). It occurs in approximately 1 in 450 males. Klinefelter syndrome is associated with androgen deficiency, infertility in males, and tall stature (Bourke, Herlihy, Snow, et al., 2014).

Klinefelter syndrome may be diagnosed when the onset of puberty is delayed or an abnormal progression is evident. Testes are small and firm. Less facial and body hair may develop. Gynecomastia is a characteristic finding (Bourke et al., 2014).

Klinefelter syndrome may also be diagnosed during the school-age years when the child is having difficulty at school. The child may have delayed developmental milestones and a low verbal IQ. Language and learning problems including difficulty reading may be present. The child may have difficulty socializing with others and body image issues (Bourke et al., 2014).

Chromosomal analysis revealing one or more extra X chromosomes confirms the diagnosis. The goal of treatment is to stimulate masculinization and the development of secondary sex characteristics when adolescence is delayed. Testosterone replacement is begun at puberty when the male is 11 or 12 years of age. A testosterone preparation is given by intramuscular injection every 3 to 4 weeks to maintain serum testosterone levels within the normal range. The dose is increased gradually every 6 to 9 months until a maintenance dose is achieved in adults (Ali & Donohoue, 2016).

Nursing Management

Nursing care consists of educating the parents and child about the syndrome, evaluating the child's and family's coping mechanisms, assisting with school problems, and reinforcing the child's strengths. Encourage parents to channel their son's energy into areas that will provide opportunities for success and productive experiences. Emphasize the importance of rewarding the boy's successes in school, sports, or hobbies. Make genetic counseling available to adolescents, if indicated, because sexual functioning and fertility may be impaired.

Inborn Errors of Metabolism

Inborn errors of metabolism are inherited biochemical abnormalities of the urea cycle, amino acid, or organic acid metabolism. Therefore, protein, carbohydrate, fat, electrolyte, blood, and respiratory metabolism can be affected. Individually they are rare disorders; however, as a group they are a significant health problem in infancy.

The biochemical defect usually causes an abnormal chemical by-product to accumulate in the blood, urine, or tissues or results in a decreased amount of normal enzymes. Most disorders are associated with protein intolerance with symptoms developing shortly after formula or breast milk feedings begin.

Clinical manifestations usually occur within days or weeks of birth. Signs and symptoms may include lethargy and poor feeding, persistent vomiting, abnormal muscle tone and seizures, apnea and tachycardia, and an unusual urine or body odor (musty, sweet odor of maple syrup or burnt sugar, or cheesy or sweaty feet).

Newborn screening has been demonstrated to save lives and to prevent serious disability. The March of Dimes (2012) recommends newborn screening tests for 31 health conditions. In most states, newborn screening programs lead to the detection of several conditions before symptoms develop.

In some cases, disorders associated with inborn errors of metabolism are not detected until signs and symptoms are present. Initial laboratory tests include measurement of serum glucose, electrolytes, blood gases, and serum ammonia. Tests results make it possible to classify the disorder by the presence of hypoglycemia, metabolic acidosis, hyperammonemia, or liver dysfunction. Further diagnostic laboratory tests are then performed on newborns with positive results.

Treatment, when available, focuses on replacing or reducing the amount of the substance causing the biochemical abnormality.

Four of the more common inborn errors of metabolism—phenylketonuria, galactosemia, mitochondrial diseases, and maple syrup urine disease—are presented in this section. Congenital hypothyroidism and congenital adrenal hyperplasia, which are also considered inborn errors of metabolism, were discussed earlier in this chapter.

Phenylketonuria

Phenylketonuria (PKU) is an autosomal recessive inherited disorder of amino acid metabolism that affects the body's use of protein. It is caused by a mutation of the phenylalanine hydroxylase gene. The incidence is approximately 1 in 15,000 newborns in the United States (Araujo et al., 2013; Brosco & Paul, 2013). Approximately 275 children are born with PKU each year in the United States (Brosco & Paul, 2013). The defect results in an accumulation of phenylalanine in the blood or phenylalanine metabolites in the urine. If untreated, this disease leads to irreversible brain damage and severe intellectual disability. Phenylalanine levels above 20 mg/dL are indicative of classic PKU (Rezvani & Ficicioglu, 2016).

Children with PKU have a deficiency of the liver enzyme phenylalanine hydroxylase that normally breaks down the essential amino acid phenylalanine into tyrosine. As a result, phenylalanine accumulates in the blood, causing a musty or mousey body and urine odor, irritability, vomiting, hyperactivity, hypertonia, hyperreflexive deep tendon reflexes, seizures, and an eczema-like rash (Rezvani & Ficicioglu, 2016). Persistence of elevated phenylalanine leads to disruption of cellular processes of myelination and protein synthesis, and results in a seizure disorder and untreatable intellectual disability.

Babies appear normal at birth except for lighter skin complexion than their nonaffected siblings. If diagnosis is delayed, a mousy or musty body odor is noticed and intellectual disability may be severe. Other common findings in untreated children include microcephaly, growth retardation, enamel hypoplasia, prominent maxilla, and widely spaced teeth (Rezvani & Ficicioglu, 2016).

Screening for PKU is required by state law in all 50 states. For best results, the newborn should have begun formula or breast milk feeding before specimen collection. Early hospital discharge places newborns at risk for false-negative screening tests if screened within 24 hours of birth. Screening needs to occur no sooner than 48 hours after birth, or the test should be repeated at 1 to 2 weeks of age. If the test shows elevated levels of plasma phenylalanine, a repeat quantitative test is performed. If the second test is positive, the family is referred to an outpatient treatment center. Serum levels of phenylalanine should be measured periodically throughout life.

Phenylketonuria is treated using special formulas and a diet low in phenylalanine to keep plasma phenylalanine levels between 2 and 6 mg/dL. The diet must also meet the child's needs for optimal growth. High-protein foods (meats and dairy products) are avoided because they contain large amounts of phenylalanine. Elemental medical foods (modified protein

hydrolysates in which the phenylalanine has been removed) are used instead. The low-phenylalanine diet should be maintained throughout life for the best outcomes (Marcason, 2013).

Nursing Management

Nursing care is mainly supportive and focuses on teaching parents about the disorder and its management. The low-phenylalanine diet is a rigid, strict diet that excludes many foods. Educate the family about sources of phenylalanine, and refer the family to a registered dietician to establish an appropriate meal plan. Parents and children need a great deal of support to promote compliance. The formula and elemental medical food costs are relatively expensive. The formula is usually reimbursed by insurance, but negotiations with health plans may help parents obtain some support for medical foods. Parents of an affected child who are considering a future pregnancy and adolescents with the disorder should be referred for genetic counseling.

Galactosemia

Galactosemia, a disorder of carbohydrate metabolism, has an autosomal recessive inheritance pattern. It occurs in approximately 1 in 30,000 to 60,000 births in the United States (Screening, Technology, and Research in Genetics [STRG], 2012).

Galactosemia results from a deficiency of the liver enzyme galactose 1-phosphate uridyltransferase (GALT), one of three enzymes needed to convert galactose to glucose. The lack of enzyme leads to an accumulation of galactose metabolites in the eyes, liver, kidney, and brain, rapidly damaging the organs and causing life-threatening problems. Affected children become susceptible to gram-negative sepsis.

Early signs include poor sucking, failure to gain weight due to vomiting followed by diarrhea, hypoglycemia, and an enlarged liver. Later signs include intellectual disability, jaundice, ascites, sepsis, lethargy, seizures, hypotonia, cataracts, and coma. Babies may die within 1 month of birth without treatment, usually because of sepsis. When diagnosis is not made at birth, cirrhosis of the liver and intellectual disability progresses and becomes irreversible (Kishnani & Chen, 2016).

Routine newborn screening for galactosemia is performed in all 50 states (National Newborn Screening and Genetics Resource Center, 2014). (See the *Clinical Skills Manual* SKILLS.) Infants who are not screened at birth are identified once they become symptomatic. The diagnosis is based on history, physical examination, and laboratory tests (galactose, aspartate aminotransferase [AST], and alanine aminotransferase [ALT] levels are abnormally high). Urine specimens are checked for reducing substances (the Clinitest is positive and the Clinistix is negative) in several specimens while the infant is receiving human milk or formula with lactose.

Treatment involves placing infants on a lactose- or galactose-free formula. A lactose- and galactose-free diet must be followed for life. Calcium, vitamin D, and vitamin K supplements may be prescribed as well (STRG, 2012).

Despite compliance with the diet, complications (learning disabilities, speech defects, ovarian failure, and neurologic syndromes) develop in many children (Kishnani & Chen, 2016).

Nursing Management

Nursing management focuses on educating the parents and child about the disorder and required diet, assessing coping abilities, and providing emotional support. Refer the family to a registered dietician for diet counseling. Families must learn to screen foods for added milk solids and to avoid medications, such as antibiotics, that have lactose fillers. Calcium supplementation may be needed. Advise parents that several galactose-free cheeses are sold commercially. Because the disorder is inherited, refer the family for genetic counseling.

Mitochondrial Diseases

Mitochondrial diseases are a heterogeneous group of genetic disorders that result from a mutation in the nuclear or mitochondrial genes (Codier & Codier, 2014). It is estimated that 1 in 300 people have a genetic mutation that could affect mitochondrial function, but only a small fraction (1:5000) will develop mitochondrial disease (Codier & Codier, 2014).

Mitochondria are the cell's energy "powerhouses," producing energy through a process called *oxidative phosphorylation*, which uses glucose and oxygen to produce adenosine triphosphate (ATP) through the respiratory electron transport chain complexes I to V of the Krebs cycle (Codier & Codier, 2014). Point mutations, deletions, or duplications in mitochondrial DNA (mtDNA) can cause mitochondrial disorders that are transmitted from mothers to their children. Mitochondrial disorders can also result from mutations in the nuclear DNA (nDNA) of either parent and follow an autosomal recessive Mendelian pattern of inheritance (United Mitochondrial Disease Foundation [UMDF], 2011) (see Chapter 3 for further information about inheritance). Malfunction of the mitochondria results in the inability of the cell to produce sufficient energy and maintain metabolic regulation. Numerous mutations are known to cause mitochondrial disease. Some of the more common disorders are Leigh syndrome, Barth syndrome, Kearns-Sayers syndrome, fatty acid oxidation disease, mitochondrial encephalopathy with lactic acidosis and stroke-like episodes (MELAS), neurogenic weakness with ataxia and retinitis pigmentosa (NAEP), and Pearson syndrome (Dassler & Allen, 2014).

Mitochondrial disease may present at any age, ranging from the newborn period into childhood and adulthood, with a spectrum of possible signs and symptoms (see Table 30–8). Clinical presentation is very diverse but affects "high energy demand" organs (Codier & Codier, 2014). Hallmarks of mitochondrial disease include (1) more than one organ system involved, (2) atypical features of another type of known disease, and (3) recurrent setbacks or flare-ups during an infection or stress. Mitochondrial disease should be considered in any patient with unexplained multisystem involvement and progressive deterioration (UMDF, 2011). A single organ may be predominately affected, but a combination of dysfunction in unrelated organs, unexplained multisystem symptoms, or involvement of three or more organ systems without a unifying diagnosis should raise concern for mitochondrial disease (Codier & Codier, 2014).

Diagnosis is elusive, time consuming, laborious, and expensive, with limited evidence-based guidelines or biomarkers (Dassler & Allen, 2014). Clinical symptoms, family history, age of symptom onset, muscle biopsy, imaging, and genetic testing are considered in making a diagnosis (Dassler & Allen, 2014). Genetic testing is still in its infancy, remains expensive, and may not be covered by insurance. Many patients have delayed diagnoses or diagnoses of probable or possible mitochondrial disease.

There is no cure or well-studied pharmacologic treatment for mitochondrial disease. Treatment focuses on conserving energy; frequent intake of nutrients; regular sleep; maintaining health; maximizing mitochondrial function; symptom management; nutrition therapy; physical therapy; reducing physiologic stressors such as extremes in cold or heat; avoiding known mitochondrial toxins such as alcohol, cigarette smoke, and

TABLE 30–8 Affected Systems and Associated Symptoms of Mitochondrial Disease

SYSTEM	SYMPTOMS
Cardiovascular	Cardiomyopathy, heart block, arrhythmias, tachycardia, bradycardia
Endocrine	Short stature, diabetes mellitus, exocrine pancreatic failure, thyroid dysfunction, hypoglycemia
Eyes and ears	Vision loss and blindness, droopy eyelids, paralysis or weakness of the eye muscles, optic atrophy, degenerative eye disease, acquired strabismus, hearing loss, deafness
Gastrointestinal	Anorexia, vomiting, diarrhea, constipation, pseudo-obstruction, irritable bowel syndrome, dysphagia, dysmotility, gastroesophageal reflux, delayed gastric emptying
Genitourinary/renal	Glomerular disease, renal tubular acidosis, frequency, urgency, urinary retention
Hematologic	Bruising, bleeding, anemia, pancytopenia
Musculoskeletal	Exercise intolerance, low muscle tone, weakness, muscle pain
Neurologic	Developmental delay, cognitive disabilities, seizures, migraines, strokes, ataxia, spasticity, temperature instability, fainting, absent reflexes
Respiratory	Obstructive sleep apnea, tachypnea, dyspnea
Systemic	Fatigue, failure to gain weight

monosodium glutamate (MSG); and providing emotional care and family support (Codier & Codier, 2014; Dassler & Allen, 2014; UMDF, 2011). Nutritious foods and frequent hydration provide cells with nutrients to support mitochondrial function, while prolonged periods of fasting produce mitochondrial stress and should be avoided (Dassler & Allen, 2014). The only current pharmacologic treatments available consist of vitamin and dietary supplementation, known as a "mitochondrial cocktail" (Dassler & Allen, 2014). This cocktail often contains antioxidants such as thiamine, vitamin C, vitamin E, and alphalipoic acid, along with coenzyme Q10 (CoQ10) and levo-carnitine (Carnitor) as essential components of mitochondrial electron transport (UMDF, 2011).

Nursing Management

Nursing management for mitochondrial disease is multifaceted and includes physiologic, emotional, and spiritual care while educating parents about energy and fatigue management, nutritional support, physical therapy, acute and long-term symptom management, physiologic stress reduction, and immunizations (Codier & Codier, 2014). Multisystem care must be individualized to meet the needs of the patient. During an acute phase, nursing care involves extensive neurologic support, seizure management, cardiac respiratory support, tube feedings, nutritional supplementation, and frequent hydration. Children with the disease should usually go no longer than 8 to 12 hours without food. Infants should be fed around the clock every 2 to 4 hours. Small frequent meals are a better choice than three full meals a day. Consumption of a complex carbohydrate or protein before bed will help prevent overnight hypoglycemia. Children who are unable to sustain oral intake during an acute illness must be referred to the hospital for intravenous dextrose supplementation. Specialists should manage care during hospitalizations or surgery, especially the administration of anesthesia. Even simple infections such as otitis media or influenza can become life threatening. Long-term management includes assessment for mobility aids, home environment adaptations, educational care plans, vision and hearing aids, assessment of family functioning, stress and coping, genetic counseling, and end-of-life care. Nursing care also involves assisting parents to navigate the complex healthcare system and coordinate visits involving multiple specialists. Nurses should inquire about specific stressors related to travel, frequent hospitalizations, medical visits, school accommodations, care for siblings, and parental guilt, and suggest effective coping strategies to manage the many aspects of mitochondrial disease (Senger, 2013). If one child in the family is diagnosed with the disorder, the siblings should also be monitored or tested even if they are asymptomatic.

Maple Syrup Urine Disease

Maple syrup urine disease (MSUD) is a disorder of amino acid metabolism that has an autosomal recessive inheritance pattern (Cole, 2014). It is rare, occurring in approximately 1 in 150,000 to 1 in 185,000 of the general population, but it occurs as often as 1 in 760 in Mennonites (Burfield, Hussa, & Randall, 2012).

In MSUD leucine, isoleucine, and valine cannot be metabolized because of an enzyme defect in the branched chain of these three essential amino acids. All three amino acids are essential to form normal structures such as the hair, skin, and muscle. Accumulation of these three amino acids leads to encephalopathy and progressive neurologic impairment if left untreated (Bodamer & Lee, 2014).

Within 5 to 7 days of life, the newborn develops symptoms of poor sucking, irregular respirations, and rigidity with alternating flaccidity (Burfield et al, 2012). Ketosis and a sweet odor of maple syrup in urine are generally present when symptoms develop (Bodamer & Lee, 2014). If the child is not treated, symptoms progress to seizures, apnea, and death (Burfield et al., 2012).

All states require newborn screening for this condition (National Newborn Screening and Genetics Resource Center, 2014). Diagnosis is made with laboratory tests of the urine for positive ketones and blood tests for elevated levels of leucine, isoleucine, alloisoleucine, and valine.

Treatment during the acute stage involves removal of the branched-chain amino acids and their metabolites from the tissues and body fluids. Some critically ill infants may require dialysis to remove these compounds because their renal clearance is poor.

Lifelong treatment includes specially designed medical formulas and foods rich in amino acids, calories, vitamins, minerals, and other nutrients as prescribed. These special medical foods have the three amino acids removed. The child needs special low-protein foods that are adequate for growth with enough calories to support twice the child's basal metabolic rate. Daily urine testing is required to determine if ketones are being excreted, an indication that the body is in a catabolic state. Liver transplants have been performed in a few affected children who were subsequently able to tolerate a normal diet. The long-term prognosis of children with MSUD is guarded (Rezvani & Rosenblatt, 2016).

Nursing Management

Nursing care includes educating the family about the disorder and special dietary requirements. The parents need to learn how to mix the child's special formula with a natural protein source, amino acid supplements, and water. The child needs formula even when ill. Parents should have a sick-day plan to prevent ketoacidosis. The child should be permitted moderate exercise only to prevent increases in leucine levels. Help families identify sources of information or support groups who can share recipes and tips for managing the child's condition.

Chapter Highlights

- The hypothalamic-pituitary axis produces several releasing and inhibiting hormones that regulate the function of many endocrine glands.
- Puberty is the process of sexual maturation that occurs when the gonads secrete increased amounts of the sex hormones estrogen and testosterone, resulting in the development of primary and secondary sexual characteristics.
- Children with hypopituitarism have short stature as a result of growth hormone deficiency. Treatment with growth hormone early in life enables these children to potentially attain genetically appropriate heights.
- An excessive secretion of growth hormone or hyperpituitarism may cause children to have tall stature, growing up to 7 or 8 feet in height if no intervention is provided before the epiphyseal plates close.
- Diabetes insipidus is a disorder of the posterior pituitary gland and is defined as an inability of the kidneys to concentrate urine.
- Syndrome of inappropriate antidiuretic hormone (SIADH) results from an excessive amount of serum antidiuretic hormone (ADH), leading to water intoxication and hyponatremia.
- Precocious puberty is defined as the appearance of any secondary sexual characteristics before 8 years in girls and 9 years in boys. If no treatment is provided, the hormones will stimulate closure of the epiphyseal plates and the child will have short stature as an adult.
- Untreated or ineffectively treated congenital hypothyroidism results in impaired growth and intellectual disability.
- Signs of hyperthyroidism include an enlarged, nontender thyroid gland (goiter), prominent or bulging eyes , eyelid lag, tachycardia, nervousness, increased appetite with weight loss, emotional lability, moodiness, heat intolerance, hypertension, hyperactivity, irregular menses, insomnia, tremor, and muscle weakness.
- During infancy, most cases of endogenous Cushing disease are due to a functioning adrenocortical tumor. The most common cause of endogenous Cushing syndrome in children older than 7 years of age is Cushing disease, in which a pituitary tumor (adenoma) secretes excess ACTH.
- Congenital adrenal hyperplasia has two forms, salt-losing or non–salt-losing with virilization. The salt-losing form accounts for 75% of cases and is caused by aldosterone deficiency and overproduction of androgen. The non–salt-losing form accounts for the other 25% of cases.
- Congenital adrenal hyperplasia is the most common cause of pseudohermaphroditism (ambiguous genitalia) in newborn girls.
- Adrenal insufficiency, also known as *Addison disease*, is a rare disorder in childhood characterized by a deficiency of glucocorticoids (cortisone) and mineralocorticoids (aldosterone). Symptoms include weakness, fatigue, weight loss, and gastrointestinal symptoms such as nausea, vomiting, diarrhea, constipation, and abdominal pain. Other symptoms include hyperpigmentation, hypotension, dizziness, joint pain, salt cravings, and hypoglycemia.
- Pheochromocytoma is a tumor that arises from the adrenal gland and causes an excessive release of catecholamines. Clinical manifestations include hypertension, palpitations sweating, anxiety, tremors, and headache.
- Diabetes mellitus type 1 is the most common metabolic disease in children and one of the most common chronic diseases in school-age children. It is a disorder of carbohydrate, protein, and fat metabolism.
- Treatment of the child with diabetic ketoacidosis includes intravenous fluids and electrolytes for dehydration and acidosis. Insulin is given by continuous infusion pump to decrease the serum glucose level at a slow but steady rate to prevent the development of cerebral edema.
- Common causes of hypoglycemia in children with type 1 diabetes include an error in insulin dosage, inadequate calories because of missed meals, or exercise without a corresponding increase in caloric intake.
- Type 2 diabetes mellitus is a condition that results from insulin resistance. Children most commonly affected are obese, and many have family members with the same type of diabetes.
- Secondary amenorrhea is the cessation of spontaneous menstrual periods for at least 120 days and occurs 6 months or 3 cycles after menarche.

- Turner syndrome is diagnosed definitively by a karyotype. The most common and most severe phenotype is 45,X indicating an absent X chromosome.
- Signs of Klinefelter syndrome include gynecomastia, delayed onset of puberty with an abnormal progression, decreased testicular size, and less facial and body hair than normal.
- Inborn errors of metabolism—inherited biochemical abnormalities of the urea cycle and amino acid and organic acid metabolism—often have a significant impact on the endocrine system's ability to support growth and development. These disorders include phenylketonuria, galactosemia, defects in mitochondrial diseases, and maple syrup urine disease.
- Children with phenylketonuria (PKU) have a deficiency of the liver enzyme phenylalanine hydroxylase that normally breaks down the essential amino acid phenylalanine into tyrosine.
- Galactosemia results from a deficiency of a liver enzyme needed to convert galactose to glucose. This leads to an accumulation of galactose metabolites in the eyes, liver, kidney, and brain, rapidly damaging the organs and causing life-threatening problems.
- Mitochondrial diseases are a group of genetic disorders resulting from a mutation in the nuclear or mitochondrial genes.
- Maple syrup urine disease is a rare disorder in which leucine, isoleucine, and valine cannot be metabolized because of an enzyme defect in the branched chain of these three essential amino acids.

Clinical Reasoning in Action

Fourteen-year-old Amanda is admitted to the hospital with newly diagnosed type 1 diabetes mellitus. She had initially been taken to her healthcare providers's office for enuresis, polyphagia, polydipsia, and lethargy, but when assessed, her urinalysis had glucose and ketones, and she had a weight loss of 15 lb.

Upon admission to the hospital, a full assessment is performed and the following vital signs are documented: weight 115 lb, temperature 98.8°F, respiratory rate 40 breaths per minute, heart rate 90 beats per minute, and blood pressure 106/63 mmHg. She has dry mucous membranes, but skin turgor is brisk. Blood is drawn immediately and will continue to be drawn every hour until she is stable.

After Amanda's condition stabilizes, education related to management of type 1 diabetes is initiated for Amanda and her parents. Amanda understands the nutritional guidelines associated with type 1 diabetes and how, under adult supervision, to perform blood glucose monitoring as well as how to draw up and administer insulin. Amanda and her parents spend most of the time in the hospital learning survival skills for managing her diabetes. Daily education and monitoring will occur in the diabetes clinic until the family is confident about taking care of Amanda. Regular follow-up visits will be scheduled with the diabetes nurse educator and endocrinologist.

1. What is the blood work most likely to be done on Amanda when admitted to the hospital for type 1 diabetes?
2. How should the family be told to manage hypoglycemic episodes?
3. What should the parents be told about preventing diabetic ketoacidosis in Amanda?
4. How often should blood glucose monitoring be performed once the condition is stabilized?

Chapter 31
Alterations in Skin Integrity

George Doyle/Getty Images

I didn't know that hot soup could cause such a bad injury. I am worried about the scars Shanelle might have over her chest from this scald burn.

—Mother of Shanelle, 1 year old

Learning Outcomes

31.1 Classify the characteristics of skin lesions caused by irritants, drug reactions, mites, infection, and injury.

31.2 Differentiate among the stages of wound healing.

31.3 Compare skin conditions that have a hereditary cause or predisposition.

31.4 Plan the nursing care for the child with alterations in skin integrity, including dermatitis, infectious disorders, and infestations.

31.5 Prepare an education plan for adolescents with acne to promote self-care.

31.6 Summarize the process to measure the extent of burns and burn severity in children.

31.7 Develop a nursing care plan for the child with a full-thickness burn injury.

31.8 Contrast preventive strategies to reduce the risk of injury from burns, hypothermia, bites, and stings.

Skin Lesions

Skin lesions vary in size, shape, color, and texture. The two major types of skin lesions are primary lesions and secondary lesions. Primary lesions arise from previously healthy skin and include macules, patches, papules, nodules, tumors, vesicles, pustules, bullae, and wheals. (See *Pathophysiology Illustrated: Common Primary Skin Lesions and Associated Conditions* in Chapter 5.) Secondary lesions result from changes in primary lesions. They include crusts, scales, **lichenification** (thickening of the skin with more visible skin furrows), scars, keloids, excoriation, fissures, erosion, and ulcers. It is important for the nurse to be able to identify and describe the primary and secondary skin lesions and understand their underlying cause and treatment.

Text continues on page 903

FOCUS ON:
The Integumentary System

Anatomy and Physiology

The skin is the largest organ in the body and performs several essential functions. The skin protects underlying tissues from invasion by microorganisms and from trauma. The nerves in the skin enable the perception of touch, pain, pressure, heat, and cold. The skin also assists the body to conserve heat by constricting blood vessels. Dilation of blood vessels and the secretion of sweat by the eccrine sweat glands enable the body to release excess heat. The sweat glands, secreting a solution of water, electrolytes, and urea, also help rid the body of toxins. The skin supplements the body's intake of vitamin D by synthesizing this vitamin from ultraviolet light.

The skin has three distinct layers: the epidermis, the dermis, and the subcutaneous fatty layer that separates the skin from the underlying tissue (Figure 31–1). The epidermis is the thin, rapidly growing, outermost layer of skin. Skin is continually shed by the stratum corneum, the superficial layer of the epidermis. The thickness of the epidermis varies by location on the body (e.g., 0.3 mm on the eyelids and 1.5 mm on the soles of the feet) (Rote, Huether, & McCance, 2014). The epidermis contains the melanocytes that synthesize and secrete melanin when the skin is exposed to ultraviolet light. The Langerhans cells within the epidermis initiate the skin's immune response when exposed to environmental antigens.

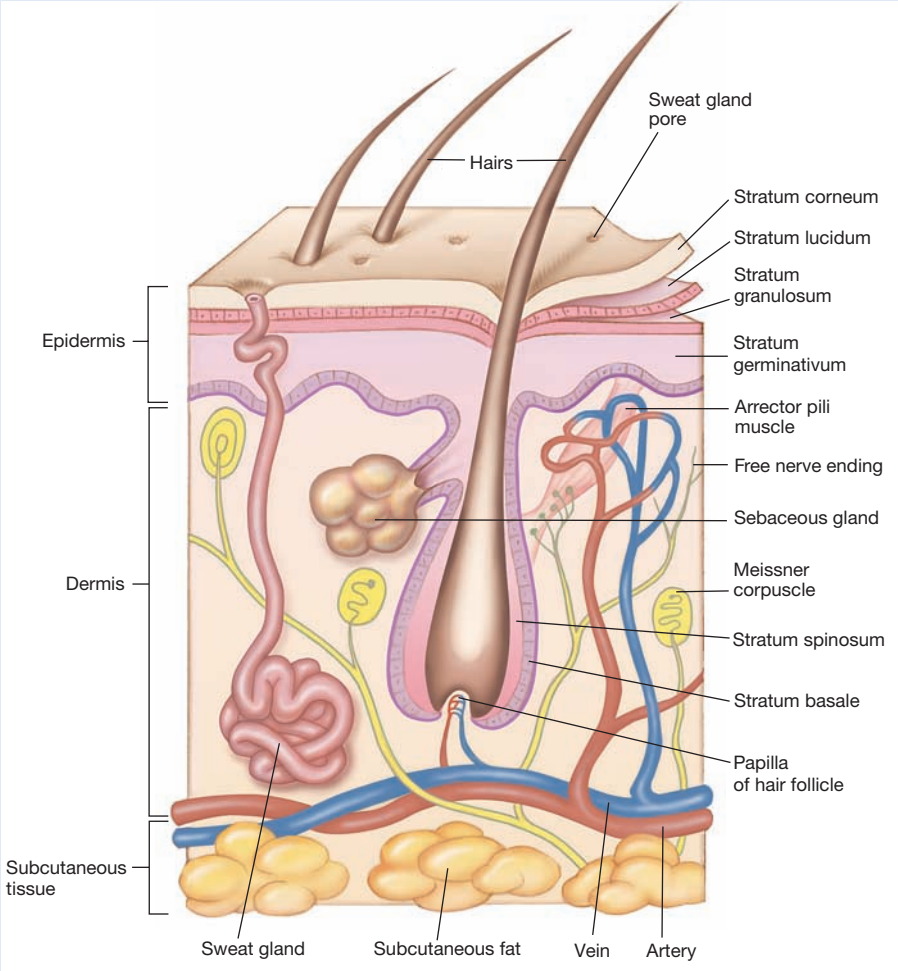

Figure 31–1 Layers of the skin with accessory structures.

The dermis, the middle layer of the skin, is mostly composed of connective tissue, which allows the skin to stretch and contract with movement. Nerves, muscles, hair follicles, sebaceous and sweat glands, lymph channels, and blood vessels are all contained within the dermis. Mast cells located within the dermis play a role in the skin's hypersensitivity reactions.

The third skin layer, the subcutaneous layer, connects the dermis to the muscle below. This layer of fat cells helps insulate the body from cold temperatures. The sebaceous glands appear all over the body except on the palms of the hands and the soles of the feet and are connected with hair follicles in most cases. Sebum, a lipid substance produced and secreted into the hair follicle or directly onto the skin, lubricates the skin and hair.

Eccrine sweat glands, located in the dermis, open onto the skin's surface. They secrete sweat, an odorless, watery fluid containing sodium, chloride, urea, and other body wastes. As the body temperature elevates, an increased production of sweat evaporates and cools the body.

Apocrine sweat glands are primarily located in the axillary and genital areas, and their secretions contain more lipids and proteins. Decomposition of the fluid secreted by these glands leads to body odor.

Pediatric Differences

The newborn's skin is the largest organ of the body, but it is thinner and more fragile than adult skin. With thinner skin and less subcutaneous fat, the infant loses heat more rapidly, has greater difficulty regulating body temperature, and becomes more easily chilled than an older child or an adult. The thinner skin also increases the potential absorption of topical medications. The infant's skin contains more water than an adult's

As Children Grow: **Integumentary System Changes**

Newborns
Skin is very thin
Epidermis is loosely bound to the dermis, friction can cause separation of the layers with blistering
Eccrine sweat glands function, produce sweat in response to heat and emotional stimuli
Apocrine sweat glands are small and nonfunctional
Less melanin is present at birth so skin is lighter colored

Adolescents
Skin thickens
Epidermis and dermis are tightly bound, increasing resistance to infection and irritation
Eccrine sweat glands achieve full function, after puberty males sweat more than females
Apocrine sweat glands mature during puberty
Melanin is at adult levels, determining skin color and serving as a shield against ultraviolet radiation

The structures of the skin mature during childhood, reaching adult function at puberty.

and has loosely attached cells. As the infant grows, the skin toughens and becomes less hydrated, making it less susceptible to bacteria (see *As Children Grow: Integumentary System Changes*).

Melanin, a peptide synthesized by an enzyme in melanocytes, influences skin color. Melanin production is low at birth and during the newborn period, accounting for the lighter skin in newborns of all races. Newborns and young infants are therefore more susceptible to damage from the sun and ultraviolet light.

Sebaceous glands and eccrine sweat glands are functional at birth in a term infant, although somewhat immaturely. The apocrine glands do not function until puberty.

Use *Assessment Guide*: *The Child With a Skin Condition* to perform a nursing assessment of the integumentary system. A list of diagnostic and laboratory tests used to evaluate skin conditions is provided in Table 31–1.

TABLE 31–1 Diagnostic Tests and Procedures for Integument Evaluation

DIAGNOSTIC PROCEDURES	LABORATORY TESTS
Culture of wound or skin drainage	Complete blood count
Tissue biopsy	Immunoglobulin E
Computed tomography (CT)	Potassium hydroxide on skin scrapings
Radiograph	
Ultrasound	

Note: See Appendices D and E for more information about these tests and procedures.

ASSESSMENT GUIDE | The Child With a Skin Condition

Assessment Focus	Assessment Guidelines*
Skin characteristics	• Inspect the skin for color, elevations, and imperfections. • Palpate the skin for texture, moisture, temperature, turgor, and edema.
Hair	• Inspect the scalp hair for color, distribution, and cleanliness. Inspect for nits (lice eggs) that adhere to the hair. • Inspect for areas of hair loss, bald spots, or broken hairs.
Lesions	• Describe skin lesions according to the characteristics listed in *Pathophysiology Illustrated: Common Primary Skin Lesions and Associated Conditions* in Chapter 5 and Table 31–2. Note erythema, signs of scratching (excoriation), or secondary infection. • Identify the location and distribution of lesions on the body (e.g., generalized, diaper area, flexor surfaces). • Palpate lesions for induration and temperature. • Measure the size of lesions (length, width, and height when appropriate).
Pain	• Assess level of pain when present.
Temperature	• Assess the body temperature.
Family history	• Identify family members with allergies or chronic skin conditions.

*See Chapter 5 for examination techniques.

TABLE 31–2 Common Secondary Skin Lesions and Associated Conditions

LESION NAME	DESCRIPTION	EXAMPLE
Burrow	A narrow, raised irregular channel caused by a parasite	Scabies
Comedone	A plug of sebaceous and keratin material in a hair follicle	Acne
Crust	Dried residue of serum, pus, or blood	Impetigo
Erosion	Loss of superficial epidermis; moist but does not bleed	Ruptured chickenpox vesicle
Excoriation	Abrasion or scratch mark	Scratched insect bite
Fissure	Linear crack in skin	Tinea pedis (athlete's foot)
Keloid	Overdevelopment or hypertrophy of scar that extends beyond wound edges and above skin line because of excess collagen	Healed skin area following traumatic injury
Lichenification	Thickening of skin with increased visibility of normal skin furrows	Atopic dermatitis (eczema)
Scale	Thin flake of exfoliated epidermis	Dandruff, psoriasis
Scar	Replacement of destroyed tissue with fibrous tissue	Healed surgical incision
Telangiectasia	Dilated, superficial blood vessels	Birthmark
Ulcer	Deeper loss of skin surface; bleeding or scarring may ensue	Pressure ulcer

Wound Healing

Wound healing occurs in three overlapping phases: hemostasis and inflammation, tissue formation, and maturation (see *Pathophysiology Illustrated: Phases of Wound Healing*).

Nursing responsibilities include wound cleansing and dressing changes. Wound cleansing is important because it removes loose material and bacteria from the site. Common cleansers are sterile water, normal saline, and commercial products that help loosen and suspend contaminants in water. Wound dressings have various properties that promote wound healing. See Table 31–3 for examples of primary dressings. Most primary dressings need a cover or secondary dressing. As the wound heals, the scar eventually achieves about 80% of the tissue's preinjury strength (Rote et al., 2014). A keloid results from an imbalance between collagen synthesis and collagen breakdown. The cause is unknown, but there is a familial tendency. A hypertrophic scar is raised but stays within the original wound boundaries.

Dermatitis

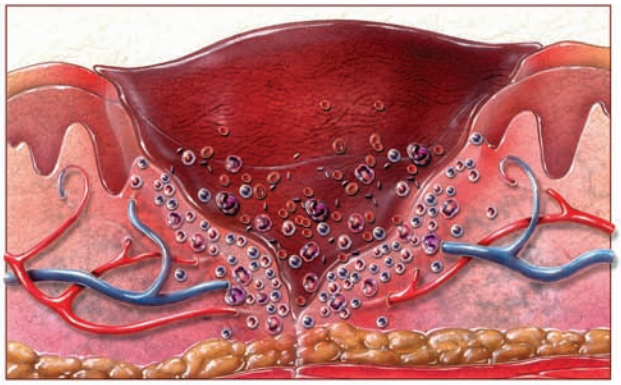
Many skin inflammations occur in early childhood. Most are easily treated and have no long-term consequences. Dermatitis is a condition in which skin changes occur in response to external stimuli. The three most common types of acute

Pathophysiology Illustrated: **Phases of Wound Healing**

Wound healing occurs in three overlapping phases:

Hemostasis and Inflammation (3–5 days)

Platelets flow to site and form a clot to stop bleeding, sealing the wound with fibrin, trapped cells, and platelets.
Platelets release inflammatory mediators (cytokines, chemokines, and growth factors).
Increased blood flow to area delivers leukocytes, phagocytes, and lymphocytes.
Increased capillary permeability causes swelling and erythema.
Bacteria are destroyed and cellular debris and foreign particles are removed.



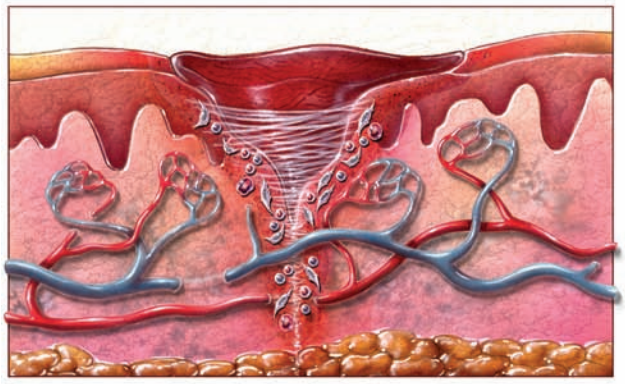
Tissue Formation (4 days to 2 weeks)

Natural debridement with fibrinolytic enzymes dissolves the fibrin clots.

Fibroblasts and endothelial cells in surrounding tissue direct the migration of cells to the newly developed fibrin matrix (replacing the clot), so remodeling can begin.

Granulation tissue forms and the wound is closed.

Capillary budding occurs for development of new blood vessels.



Maturation (months to 2 years)

Wound contraction occurs.

Epithelial cells migrate from the peripheral areas.

Collagen development leads to scar formation and strengthening.

Capillaries disappear from the scar tissue, returning the tissue to its original blood supply.

Huether, V. L. Brashers, & N. S. Rote (Eds.), *Pathophysiology: The biologic basis for disease in adults and children* (7th ed., pp. 191–223). St. Louis, MO: Elsevier.

dermatitis in infants, children, and adolescents are contact dermatitis, diaper dermatitis, and seborrheic dermatitis. See information on atopic dermatitis later in this chapter. These skin disorders may cause an emotional response in the child and family. Be supportive and reassure the family that the child is not infectious.

Contact Dermatitis

Contact dermatitis is an inflammation of the skin that occurs in response to direct contact with an allergen or irritant.

When an external irritant causes contact dermatitis, an inflammatory response occurs without an immune response. Common irritants include soaps, detergents, fabric softeners, bleaches, lotions, urine, and stool. An irritant can affect the skin any time there is adequate concentration and contact duration. Sweating and friction enhance the exposure to an irritant. Children with atopic dermatitis may be at risk for irritant contact dermatitis because of decreased skin barrier function.

Phytophotodermatitis can result when the child has skin contact with certain citrus fruits, celery, parsley, fennel, fig leaves, or ragweed. These plants have a chemical (furocoumarin) that

TABLE 31–3 Primary Wound Dressings

DRESSING TYPE	PROPERTIES	NURSING MANAGEMENT
Hydrocolloid—semiocclusive	Uses wound exudates to form a gel-like cover that adheres and protects wound bed from contaminants Maintains moist environment Promotes autolytic debridement	Use for granulating and epithelializing wounds with low or moderate amount of exudates. Use with caution in infected wounds. Cover at least 1 in. of intact skin around the wound.
Hydrogel—semiocclusive	Increases and maintains moisture content Promotes autolytic debridement Does not adhere, reducing pain with removal	Use with minimal or moderate exudate as limited exudates absorption. Cover at least 1 in. of intact skin around the wound.
Foam—semiocclusive	Absorbent—used for moderate to heavy exudate Nonadherent	Use for packing deep wounds. Use for heavy exudate when drainage is at peak.
Alginates—semiocclusive	Absorbs exudate and converts it to a gel Provides a moist environment	Use for moderate to heavy exudate. Use to pack wounds.
Transparent film—occlusive	Permeable to oxygen and water vapor Maintains moist environment Nonabsorbent Protects wound from contamination	Its use provides visible wound evaluation. Use on superficial wounds with little or no drainage or on areas of friction. Use care when removing film to prevent skin tearing.

Figure 31–2 Contact dermatitis caused by poison ivy. Note the clustered tiny erythematous papules involving the face and neck. In some areas (particularly the neck), lesions are distributed in a linear fashion.

SOURCE: Courtesy of Daniel P. Krowchuk, MD, Professor of Pediatrics and Dermatology, Wake Forest School of Medicine, Winston-Salem, NC.

sensitizes the skin to sunlight. Following sun exposure the child develops erythema and blistering at the site of the contact, and the skin then becomes hyperpigmented 1 to 2 weeks later. The hyperpigmentation fades over several months (Shulstad, 2012).

Allergic contact dermatitis is a delayed T-cell–mediated hypersensitivity reaction. An antigen is absorbed from the skin surface during the initial sensitization phase, and an immune memory is created. A repeated exposure or a long-term exposure is required to cause the immune response and the dermatitis. See Chapter 22 to review the immune response to allergens. Common allergens include poison ivy, poison oak, lanolin, neomycin, rubber, chemicals in shoe leather, nickel, fragrances, and latex (Figure 31–2). Children may have both irritant and allergic reactions to latex, which is found in many types of hospital equipment and supplies and products in the home.

With irritant contact dermatitis, a discrete area of redness is seen that corresponds to the exposure location, and severity is related to duration of exposure. The rash usually develops within a few hours of contact, peaks within 24 hours, and quickly resolves with removal of the irritant. With longer exposure, reactions may include painful erythema, edema, vesicles, and exudate.

Allergic contact dermatitis is characterized by erythema, edema, pruritus, vesicles, or bullae that rupture, ooze, and crust. The rash is usually limited to the area of contact (Table 31–4). Symptoms of allergic contact dermatitis can develop several hours following exposure, after the immune response has been activated. Symptoms can last 3 to 4 weeks without treatment.

The history of potential exposures and distribution of lesions provide clues about the source and identity of the allergen or irritant. Secondary infection may occur. For irritant contact dermatitis, treatment involves removing the offending agent (e.g., clothes, plant, soap). Use emollients to restore the skin barrier. Decrease inflammation with hydrocortisone cream or ointment. Antihistamines may help relieve itching or be given for their sedative effect.

SAFETY ALERT!

Some children have allergic contact dermatitis associated with spices such as vanilla, clove, and cinnamon, as well as citrus peels. These children may develop systemic contact dermatitis through oral ingestion of these products that are in the Balsam of Peru family of flavorings in chewing gum, toothpaste, baked goods, and food condiments. These children may need special dietary guidelines to reduce exposure to Balsam of Peru products (Fonacier et al., 2012).

TABLE 31–4 Distribution of Lesions by Type of Allergen

DISTRIBUTION OF LESION	ALLERGEN
Face, eyelids, neck	Cosmetics, hair and skin care products, nail polish and cosmetics, fragrances, eyeglasses with nickel
Earlobes, area with body piercing	Jewelry with nickel, cell phone
Lips, mouth	Oral hygiene products, bubblegum, lipstick
Hands	Rubber or neoprene gloves, mouse pad
Dorsal aspects of toes and feet	Rubber or leather chemical in shoes, metal buckles on sandals
Trunk	Snaps or other metal fasteners on clothing, belt buckles, moisturizers, cleansers, sunscreen products

Source: Data from Kwan, J. M., & Jacob, S. E. (2012). Contact dermatitis in the atopic child. *Pediatric Annals, 41*(10), 422–428; Fonacier, L. S., Aquino, M. R., & Mucci, T. (2012). Current strategies in treating severe contact dermatitis in pediatric patients. *Current Allergy and Asthma Reports, 12*, 599–606; Krowchuk, D. P., & Mancini, A. J. (2012). *Pediatric dermatology: A quick reference guide* (2nd ed., pp. 43–53). Elk Grove, IL: American Academy of Pediatrics; Halloran, L. (2014). Developing dermatology detective powers: Allergic contact dermatitis. *Journal for Nurse Practitioners, 10*(4), 284–285.

Acute allergic contact dermatitis is managed with medium-potency topical corticosteroids when less than 10% of the body surface area is affected. The topical corticosteroids are applied to the affected area twice a day for 2 to 3 weeks. Do not apply the medication to open lesions. Rebound dermatitis may occur if treatment is stopped early. Reactions to poison ivy or other allergens covering more than 10% of the body surface area require oral corticosteroid treatment for 7 to 14 days and a tapered dose for 7 to 10 additional days.

Nursing Management

Assess the child's skin using guidelines found earlier in the chapter in *Assessment Guide: The Child With a Skin Condition*. Family education for home care management focuses on care of the skin and prevention of future exposures. Teach parents how to apply topical corticosteroids and to keep using the medication for 2 to 3 weeks even when the skin shows signs of healing. Wet dressings may be soothing and help loosen crusts. Burow solution used as a soak helps dry lesions. Familiarize parents with the symptoms of infection in the affected area (i.e., increased redness, oozing, fever) and tell them when to return for follow-up care.

Teach parents to avoid exposure to allergens or irritants. Advise parents to wash all clothes before the first wearing and to rinse clothes an extra time to remove all the soap. Mild soap should be used to clean the skin. An emollient may be used for dry skin. Place a barrier between the irritant (e.g., metal, shoe leather) and the skin. If a nickel allergy exists, avoid use of nickel jewelry and belt buckles.

Diaper Dermatitis

Diaper dermatitis, a common cause of irritant contact dermatitis, occurs in approximately one third of young children, usually in a mild form. It is more common in infants from 9 to 12 months and toddlers.

Diaper dermatitis is a primary reaction to urine, feces, moisture, or friction. Urine and feces interact with the skin to cause dermatitis. The urine increases the wetness and pH of the skin, increasing abrasion and its permeability to irritants and microbes. Urine also metabolizes to ammonia, producing another irritant. Fecal organisms provide more irritants.

Infection with *Candida albicans* is a common complication of diaper dermatitis or antibiotic therapy for another condition. It is frequently the underlying cause of severe diaper rash. Diaper candidiasis often occurs simultaneously with oral candidiasis.

The rash is characterized by raw, moist, or weeping macules and papules of the skin in direct contact with the diaper. The skinfolds are usually spared. In severe cases, the infant develops a rash that is fiery red, raised, and confluent (Figure 31–3). Pustules with tenderness can also be present. When a *C. albicans* infection occurs, the rash has bright-red beefy plaques with sharp margins that may rupture and leave scales. Small papules and pustules may be seen, along with satellite lesions. Skinfolds may be affected.

Families Want to Know

Exposure to Poison Ivy or Poison Oak

- The rash is caused by contact with urushiol, a resin of the plants, either directly or indirectly, such as transfer from an animal or clothing. Avoid hugging a pet exposed to poison ivy until after the pet has been bathed. Once the rash develops, it is not contagious.
- Wash exposed skin with soap and water, and scrub under the nails as soon as possible after contact. Zanfel and Ivy X are over-the-counter products that remove urushiol after poison ivy exposure to reduce itching and severity of rash if used promptly.
- Do not rub fingers exposed to poison ivy against broken skin or the eyes.
- Launder clothing worn during exposure, and wash hands after handling exposed clothing.
- Wear vinyl gloves to handle plants (cloth and rubber gloves allow sap to penetrate).
- Search the yard and remove all plants. Do not burn plants removed. A person with a sensitivity may inhale the smoke and develop severe airway inflammation.
- For children with sensitivity to poison ivy, an over-the-counter barrier cream such as Ivy X preexposure solution can be applied to help prevent skin penetration of plant oil.

Figure 31–3 Diaper dermatitis. Note the skinfold that is free of inflammation.

SOURCE: Courtesy of the Centers for Disease Control and Prevention, Atlanta, GA.

Mild diaper dermatitis is treated with a water-impermeable barrier or protective sealant such as zinc oxide, Aquaphor, Desitin, or Balmex after every diaper change. In some cases, a diaper ointment combined with a protective powder (e.g., karaya powder) may be effective. An antifungal topical medication (e.g., nystatin) is applied to the skin before the barrier product when *C. albicans* is present, and is continued for 3 days after the rash clears. Topical corticosteroids are often avoided for diaper dermatitis because occlusion in the diaper area increases corticosteroid systemic absorption. If topical corticosteroids are necessary, a low- potency product is used.

Nursing Management

Diaper dermatitis can be a major source of stress for parents when the child is in constant discomfort. Instruct parents to change the diaper as soon as the infant is wet, or at least every 2 hours during the day and once during the night to minimize contact with urine and fecal irritants. Teach parents to apply barrier products and to remove them once or twice a day so fresh medication can be applied. Mineral oil and a soft cloth are effective for removing pastes. Encourage the parents to return for further care if the infant's skin is not greatly improved within a week.

Encourage parents to use superabsorbent disposable diapers, which tend to reduce the frequency and severity of diaper dermatitis. When wet, these diapers form a gel that keeps the skin drier than cloth diapers; however, diapers should still be changed every 2 to 3 hours. Exposing the diaper area to air aids healing. For example, allow the infant to go without a diaper while lying on an absorbent pad or cloth.

Advise parents to wash the perianal area with warm water or a waterless cleanser (Aquanil HC lotion or Cetaphil) after a bowel movement. Advise parents to use soft cloths or paper towels with warm tap water or to use baby wipes without alcohol if baby wipes are preferred. Pat the skin dry to reduce friction and skin injury. Avoid using powder or cornstarch because they may increase friction.

Seborrheic Dermatitis

Seborrheic dermatitis is a recurrent inflammatory skin condition thought to be caused by an overgrowth of a yeast, *Malassezia furfur* (formerly *Pityrosporum ovale*). The condition is thought to be influenced by hormones. The rash is found over the areas of the body where the sebaceous glands are most plentiful: scalp (cradle cap), face, and postauricular and periorbital areas. The condition is frequently seen in infants up to 3 months of age and in adolescents.

Common symptoms are pruritus and a mildly erythematous, adherent, waxy scaling of the scalp (or "dandruff"). Yellow-red patches with greasy scaling may be present, typically on the scalp and nasolabial folds on the face, behind the ears, on the upper chest, and sometimes on the **intertriginous** (skinfolds of the neck, axillae, antecubital fossa) areas (Figure 31–4). Itching is less intense than with atopic eczema.

Treatment for young infants consists of daily shampooing with baby shampoo. An **emollient**, a topical product that soothes and softens the skin, such as warm mineral or olive oil, is left on the scalp for about 20 minutes to soften the crusts after shampooing. The scales are removed by brushing with the fingertips or a soft toothbrush. The hair is then shampooed again and rinsed thoroughly. A shampoo with 2% ketoconazole may be used in infants if baby shampoo is not effective (Ooi & Tidman, 2014).

Lesions on the body of adolescents can be treated with shampoos containing selenium sulfide or salicylic acid. Use baby shampoo to wash lesions on the eyelids and eyelashes. Treatments are continued for several days after the lesions disappear and may be repeated weekly to prevent recurrence. Topical corticosteroids are used to treat seborrhea that is not on the scalp, but avoid its use around the eyes.

Nursing Management

Teach new parents to wash the infant's hair daily with each bath. Reassure parents that gentle cleansing will not harm the infant's "soft spot." Demonstrate bathing to show them the proper technique, if necessary. Follow-up is seldom necessary, as the condition resolves with treatment. Advise

Figure 31–4 Seborrheic dermatitis. Note the extensive red patches with scales over the forehead and face.

adolescents that emotional distress may trigger future flare-ups and to initiate treatment promptly when symptoms begin.

Bacterial Infections

Impetigo

Impetigo, the most common bacterial skin condition, is a highly contagious, superficial (epidermal) infection. The most common sites are the face, around the mouth, the hands, the neck, and the extremities. Minor skin injuries, insect bites, and dermatitis provide the portal for the infectious agent. Impetigo occurs more commonly in children who are in close physical contact with others, such as in childcare settings, or in those who have poor hygiene.

Either group A beta-hemolytic streptococcus, *Staphylococcus aureus*, or both together are usually responsible. *S. aureus*, the more common organism, colonizes on the skin and in the nose and throat. Some children will pick their nose and infect themselves. Bullous impetigo results from a strain of *S. aureus* that produces an exfoliative toxin that blisters the epidermis.

The impetigo lesion begins as a papule that turns into a vesicle at the injury site. The vesicle ruptures and forms an erosion, and serous fluid forms the characteristic honey-colored crusts. Pruritus and regional lymphadenopathy may be present. The rash may spread to the face and extremities by self-inoculation (Figure 31–5). In bullous impetigo, vesicles stimulated by a toxin enlarge and coalesce to form bullae with sharp margins and no surrounding erythema. A thin honey-colored crust forms when the bullae rupture. When the crust is removed, a moist, erythematous lesion with a collar of skin around the erosion is seen. These lesions occur more commonly in moist skinfold areas. Impetigo is diagnosed by appearance or lesions or by bacterial culture.

Local treatment of nonbullous impetigo involves removal of the crusts and application of a topical antibiotic. A topical bactericidal ointment such as mupirocin or retapamulin is applied 3 times a day for 5 days (Stevens et al., 2014). Oral antibiotics are prescribed for bullous impetigo. Skin generally heals without scars. The infection is communicable for 24 hours after antibiotic ointment treatment is begun.

Figure 31–5 Impetigo. Note the honey-colored crusts over the lesion.

SOURCE: Dr. P. Marazzi/Science Source.

Potential complications are postinfectious streptococcal glomerulonephritis (see Chapter 26) and cellulitis.

Nursing Management

Teach parents to soak crusts in warm water and gently scrub them off with a gauze pad and antiseptic soap prior to using topical ointment. Teach parents to dispose of the gauze pad in a plastic bag to avoid spreading the infection to other family members. Advise parents to continue using the topical or oral medication for the full number of days prescribed. Inform the parents to observe all close contacts and family members for lesions. The infected child should not share towels or toiletries with others, and all linens and clothing used by the child should be washed separately with detergent and hot water. Keep fingernails short and clean to prevent spreading infection by scratching. Inform the childcare center about the infection, so staff can sanitize toys and surfaces.

Community-Acquired Methicillin-Resistant *Staphylococcus aureus*

Community-acquired, methicillin-resistant *Staphylococcus aureus* (CA-MRSA) may cause a severe and aggressive skin and soft-tissue infection in healthy children. CA-MRSA is colonized on the skin, the mucous membranes, and nares of healthy individual carriers. Direct contact transmission and respiratory droplet transmission occur. Athletes are at high risk because of their potential for frequent skin-to-skin contact, cuts or abrasions, wound contact, and shared items.

Clinical manifestations include furuncles or abscesses that may invade deeper tissues. Localized swelling, redness, warmth, purulent drainage, fever, and pain may be present.

Incised abscesses are cultured to diagnose CA-MRSA. Simple abscesses are treated with incision, drainage, wound care, and systemic antibiotics. Children with repeated CA-MRSA infections may be encouraged to decolonize the skin to reduce the number of infections.

Clinical Tip

When the child has recurrent CA-MRSA infections, the child or family member may be a nasal carrier of *S. aureus*. All household members may be treated with nasal application of mupiricin 2 times a day for 5 days and bathe with diluted bleach solution (one half cup to a tub one quarter full) or chlorhexidine scrub for 5 days. Surfaces frequently touched and bed linens must be decontaminated. A second round of household treatment may be needed (Fritz et al., 2012).

Nursing Management

Ensure that parents and adolescents understand the importance of taking the full course of the prescribed antibiotic. Educate parents about meticulous wound care to prevent the spread of CA-MRSA:

- Keep the wound and drainage completely covered at all times.
- Change the dressing twice a day using vinyl gloves. Use good hand hygiene before and after dressing changes.

- Dispose of used dressings in a tightly closed plastic bag.
- Disinfect surfaces that come into contact with the wound or wound drainage using a bleach solution.
- Use hot water to wash linens and clothing used by the child, and dry clothes in a hot dryer.

Nurses have a major role in prevention of CA-MRSA infections. Nurses in contact with the wound should remove gloves before touching and contaminating surfaces in the examining room. Ensure that any equipment and linen used by the child are appropriately managed and the examining room is cleaned with an effective agent.

Educate parents, adolescents, coaches, and teachers about the importance of a regular schedule for cleaning equipment and having athletes take showers with soap and water after all practice sessions. Discourage athletes from sharing towels and clothing. Cover minor wounds to reduce exposure to other athletes. Skin infections that worsen rather than heal with regular topical antibiotics should be seen by a healthcare provider.

Folliculitis

Folliculitis is a superficial inflammation of the pilosebaceous follicle caused by infection, trauma, or irritation. The causative organism is usually *Staphylococcus aureus*. The condition is common in children and teenagers because of increased sweat production. Folliculitis may be associated with *Pseudomonas aeruginosa* exposure in a poorly chlorinated pool or hot tub.

Symptoms include pain or pruritus, localized swelling, and the formation of tiny dome-shaped, yellowish pustules and red papules at follicular openings with surrounding erythema. Individual lesions may become deeper and form an abscess (furuncle). Lesions are usually seen in clusters on the face, scalp, trunk, and extremities. Some children have fever, aching, and flulike symptoms. If associated with *Pseudomonas* exposure in a pool or hot tub, lesions may develop on areas covered by bathing suits.

Folliculitis is treated by washing the affected area with a topical antibacterial cleanser (e.g., chlorhexidine) and water. A benzoyl peroxide gel or wash or another drying agent will also help clear the infection. Ruptured lesions heal with hyperpigmentation and no scarring. Complications are rare. If the child or adolescent has systemic symptoms, oral antibiotics (e.g., clindamycin or doxycycline) may be prescribed. If a furuncle develops, incision and drainage may be needed. Children who are immunocompromised should not use hot tubs because of the potential for complications from *Pseudomonas*.

Nursing Management

Nursing management focuses on educating the parents and child about prevention. Advise children to shower daily and shortly after exercise, to cleanse with an antibacterial soap, and to wear loose cotton clothing. Talk with parents about the importance of maintaining the correct pH level and chlorine concentration in swimming pools and hot tubs. Bathing suits of affected children should be laundered and dried well before the next use.

Cellulitis

Cellulitis is an acute inflammation of the loose connective and subcutaneous tissues and the dermis. The condition usually occurs on the face and extremities as a result of trauma or a compromised skin barrier.

ETIOLOGY AND PATHOPHYSIOLOGY

The child may have a history of trauma, surgery, or skin lesions. Common causative organisms are *Staphylococcus aureus* and *Streptococcus pyogenes*. The condition may also result from a nearby abscess or sinusitis. Onset is usually rapid.

CLINICAL MANIFESTATIONS

Children with cellulitis have a rapid onset and they appear ill. Classic signs and symptoms include red or lilac, tender, warm, edematous skin around the infected site (Figure 31–6). The border is often indistinct because the infection is deep in the tissue. Other symptoms include fever, chills, malaise, and enlargement and tenderness of regional lymph nodes. **Lymphangitis**, inflammation of the lymphatic system draining the site of infection (seen as tender, erythematous streaks extending in a proximal direction), may be present.

CLINICAL THERAPY

Blood studies may show an increase in white blood cells. Cultures are taken by needle aspiration to identify the causative organisms. Blood cultures and a lumbar puncture are performed if the child has a toxic (very ill) appearance (see the *Clinical Skills Manual* SKILLS).

Children with severe cases or involvement of the face or a large affected surface area are hospitalized and treated aggressively with IV antibiotics and analgesics to avoid serious complications, such as sepsis, necrotizing fasciitis, or osteomyelitis. Children with less severe cellulitis on the trunk, limbs, or perianal area may be treated on an outpatient basis with oral antibiotics. Recovery begins within 48 hours, but therapy should continue for at least 10 days (Juern & Drolet, 2016). See Chapter 19 for treatment of periorbital cellulitis.

Figure 31–6 Characteristic appearance of cellulitis with borders of extensive inflammation outlined.

SOURCE: Courtesy of Daniel P. Krowchuk, MD, Professor of Pediatrics and Dermatology, Wake Forest School of Medicine, Winston-Salem, NC.

Nursing Management

Assessment centers on recognition of the severity of infection, documentation of location and related symptoms, and monitoring of vital signs. Administer prescribed oral or IV antibiotics as scheduled. Supportive care includes warm compresses to the affected area 4 times daily, elevation of the affected limb, and bed rest. Outpatient follow-up is crucial to ensure response to therapy.

Advise parents about possible complications, such as abscess formation. Instruct parents of children treated at home to contact their healthcare provider if the child has any of the following signs:

- Spread of the infected area in the 24- to 48-hour period after the start of treatment
- Temperature over 38.3°C (101.0°F)
- Increased lethargy

Reinforce to parents the importance of compliance with the treatment regimen and the seriousness of the possible complications.

Viral Infections

Molluscum Contagiosum

Molluscum contagiosum is a skin infection caused by a poxvirus. It is transmitted by direct contact, contact with contaminated objects, or sexual contact. Spread occurs by autoinoculation. The incubation period is 2 to 7 weeks (American Academy of Pediatrics [AAP], 2015, p. 561. Children 2 to 11 years of age are most commonly affected, but increased risk is believed to be associated with atopic eczema and immunodeficiency.

Multiple pearl-like flesh-colored smooth papules (usually less than 30) are about 2 to 5 mm (0.08 to 0.2 in.) in size. The lesion has a central depression, and a plug of cheesy material can be expressed when punctured. Lesions may appear anywhere on the body, but are more often found on the face, trunk, and extremities. Adolescents may have lesions on the genital mucous membranes. If children have genital lesions, consider sexual abuse as a possible source of infection.

Supportive care is often preferred because aggressive treatments frequently cause scars or hyperpigmentation in children with darker skin. A single lesion may be present for 2 months, but the usual duration of the condition is 8 to 12 months, resolving spontaneously. Emollients, topical corticosteroids, or oral antihistamines are used for pruritus. When treatment is provided, options to destroy lesions include curettage, **cryotherapy** (freezing each lesion with liquid nitrogen), or pulsed-dye laser. Topical anesthesia is needed for curettage. Other treatment options include chemical treatment (e.g., salicylic acid or cantharidin), an immune modulator (e.g., imiquimod), or antiviral medication. No one treatment has demonstrated better effectiveness (Chen, Anstey, & Bugert, 2013). Secondary infections are a potential complication.

Nursing Management

Nursing education focuses on reducing disease transmission. Infected children should not use public swimming pools, hot tubs, or bathe with other children because the virus is more easily transmitted when the skin is wet. Transmission of the virus among household members is high. Towels, sponges, and clothing should not be shared. Wash the skin daily with gentle fragrance-free cleansers. Apply a hypoallergenic moisturizer or emollient to the entire skin surface. Teach parents to recognize potential secondary infections.

When intervention such as curettage or cryotherapy is performed, ensure that adequate topical anesthetic is used to minimize pain. Inform the child about what will happen, and provide distraction during the procedure to reduce anxiety.

Warts (Papillomavirus)

Warts commonly are found in children between 1 and 17 years, with a prevalence of 3.3% in the United States. The peak age is 9 to 10 years when 8.6% of children are affected (Silverberg & Silverberg, 2013). Several types of human papillomavirus infect epithelial cells and cause warts. Common warts appear on any skin surface, and plantar warts are found on the feet. The virus is commonly transmitted by direct skin-to-skin contact or mucous membrane contact. It also survives on various surfaces, and transmission can occur with contact, such as plantar warts from locker room floors. The incubation period may be 2 to 6 months; however, a latency period may exist in some cases. Children with immune compromise are more susceptible and often have numerous warts.

Common warts appear as skin-colored, rough, scaly papules and nodules on exposed skin surfaces. Individual and multiple warts may be seen, or large plaques may form if autoinoculation occurs. Warts usually cause no pain or itching unless on skin surface areas that becomes irritated. Plantar warts appear as papules and plaques on the bottom of feet that grow inward and cause pain. Small black dots result from thrombosed vessels on the surface of the warts caused by weight bearing.

No intervention may be recommended as warts often resolve spontaneously over a couple of years. Warts do not produce scarring unless treated surgically or in an aggressive manner. If warts cause pain or a social stigma, clinical therapy may be initiated. Treatment usually involves destruction by daily home application of salicylic acid plasters, and occlusion with tape is sometimes recommended. Other treatments include liquid nitrogen or pulsed-dye laser. No one treatment is fully effective. A keratolytic agent (imiquimod) may be used to treat external anogenital warts. Immunotherapy may also be used.

Nursing Management

Educate the parents and child about how warts are spread by picking at it or chewing on it. If the child will not stop sucking or chewing on the wart, bitter apple or a pepper solution may discourage the child. Teach parents about the application of peeling agents when prescribed for home use. If the reaction to the treatment is painful, encourage the parents to reduce the frequency of the treatment until the pain subsides and then to resume the original treatment schedule. Successful treatment may take several months, and parents may need encouragement to continue the therapy and remain optimistic.

Other viral skin conditions are described in Chapter 16.

Fungal Infections

Oral Candidal Infection (Thrush)

Thrush is a fungal infection, usually caused by *Candida albicans*. An acute infection may occur in newborns or in children who regularly use a corticosteroid inhaler or have received

Figure 31–7 Oral thrush is an acute pseudomembranous form of candidiasis. It is a common fungal infection in infants and children.

SOURCE: Alamy.

antibiotics that disturb normal flora. An invasive *C. albicans* infection may occur in children with either an impaired immune status (immunodeficiency) or a central venous catheter receiving long-term parenteral alimentation therapy (AAP, 2015, p. 275).

Oral thrush is characterized by white patches that look like coagulated milk on the oral mucosa and may bleed when removed (Figure 31–7). Gentle attempts to remove patches are unsuccessful, while actual milk residue can be removed with gentle swabbing. The infant may refuse to nurse or feed because of discomfort and pain. The infant may also have diaper dermatitis. Fever is usually not present.

Diagnosis is made by clinical appearance, microscopic examination of a skin scraping suspended in potassium hydroxide, or fungal culture. Treatment involves oral nystatin suspension or clotrimazole applied to the mouth and tongue after feedings. Fluconazole or itraconazole may be used for immunocompromised patients with oropharyngeal candidiasis. Intravenous amphotericin B may be used for invasive and systemic *Candida* infections.

Nursing Management

Teach parents to give the medication by swabbing the suspension on the buccal mucosa and tongue surfaces, allowing the infant to swallow the remaining suspension. Teach older children to swish the solution around in the mouth before swallowing it.

To help prevent a reinfection, educate parents to use good hand hygiene and to sterilize bottle nipples and pacifiers. Teach parents and older children with asthma to rinse the mouth well with water after using a corticosteroid inhaler. If a spacer is used, it should also be rinsed with water after use. A commercial antiseptic spray may be used on toys put in the mouth that cannot be autoclaved, but follow directions carefully so the child does not ingest any harmful residue.

Dermatophytoses (Ringworm)

Dermatophytoses are fungal infections that commonly affect the skin, hair, or nails. Children of all ages may be affected. Dermatophytoses may be spread from another person or animal or by contact with a contaminated object. See Table 31–5 for the clinical manifestations of tinea infections.

Diagnosis is confirmed through microscopic examination of the hair and scalp scrapings using a potassium hydroxide (KOH) wet mount to reveal rows and chains of spores within the hair shaft. A fungal culture can also be taken from a scalp lesion by rubbing a cotton-tipped applicator across the scalp or body lesion. Shining a Wood lamp on the lesion helps identify some forms of tinea (e.g., microsporum fluoresces a brilliant green). The most common cause of tinea, *Trichophyton tonsurans*, does not fluoresce (AAP, 2015, p. 780). See Table 31–5 for clinical therapy.

Clinical Tip

Some children treated for tinea capitis develop an "id" reaction, an extensive, itchy papulovesicular rash on the trunk, extremities, and face similar to atopic dermatitis. This is a hypersensitivity reaction to the fungal antigen, not an allergic reaction to the oral medication (AAP, 2015, p. 779). Antifungal therapy must be continued to resolve the infection.

Nursing Management

Assess all members of the family and household pets for fungal lesions. Since person-to-person transmission is common, family members should not share hair accessories, brushes, and hats. Because a family member may be an asymptomatic carrier, all family members should be treated with selenium shampoo. Teach parents and older children or teenagers that fungi are found in soil and animals and are transmitted through direct contact.

Advise parents to give oral griseofulvin with fatty foods such as whole milk or peanut butter to enhance absorption. To prevent recurrence of the infection, the medications must be used for the entire prescribed period, even if the lesions are gone. Advise parents about the possibility of the "id" reaction so they will continue to give the medication.

Parents of children with tinea capitis should be told that hair regrowth is slow and may take 6 to 12 months. In rare cases, hair loss is permanent, which can be particularly stressful for older children or adolescents. Provide emotional support. Encourage children to wear shower shoes in public showers and locker rooms to prevent tinea pedis.

Drug Reactions

Adverse reactions to over-the-counter or prescription medications are relatively common. Children with drug allergies usually have reactions after ingestion (e.g., aspirin, antibiotics, sedatives), injection (e.g., penicillin), or direct skin contact with medications. Drug sensitivities may result from variations in an individual's ability to tolerate a particular drug or concentration of a drug or from allergic responses. (See Chapter 22 for a description of allergic reactions.)

Sensitivity reactions may occur after 1 or 2 doses when the child has previously taken the drug, but it may take up to 7 days for sensitivity to occur to a drug not previously administered. The most common reactions in children are erythematous macules and papules or urticaria, which may be pruritic. Drugs that may cause a sensitivity reaction include the following: sulfonamides, anticonvulsants, antibiotics, and nonsteroidal anti-inflammatory drugs (NSAIDs). Be alert to the possibility of serious drug reactions that may become a medical emergency. See Table 31–6 for clinical manifestations of drug reactions.

TABLE 31–5 Clinical Manifestations of Tinea Infections

INFECTION SITE AND CLINICAL MANIFESTATIONS	CLINICAL THERAPY
TINEA CAPITIS (SCALP)	
Scaly pustular bald areas with indistinct margins; may appear as seborrhea, with yellow, greasy scales; erythema or lesion lighter than skin color Broken hairs; black dotted stubbed appearance where weakened hair has broken off Mild itching **Kerion**—large purulent tender boggy mass on scalp with drainage Tinea capitis. Source: Centers for Disease Control and Prevention.	Oral griseofulvin for 8–12 weeks, OR oral terbinafine for 6 weeks in children over age 4 years. Fluconazole and itraconazole are not U.S. Food and Drug Administration (FDA) approved in children under 12 years of age. Selenium sulfide or ketoconazole shampoo 2–3 times weekly, leaving the shampoo on the scalp for 10 min before rinsing. Encourage family members to use the shampoo 2–3 times a week to reduce the number of fungal spores in the household. For kerions with evidence of secondary bacterial infection, antibiotics are added to oral antifungal agents (AAP, Committee on Infectious Disease, 2015, p. 781).
TINEA CORPORIS (TRUNK)	
Pink, scaly circular patch with an expanding border, may be scaly or erythematous throughout; slightly raised borders with a clearing center Usually acquired from contact with infected human, animal, or contaminated object (e.g., hat) Tinea corporis. Source: Centers for Disease Control and Prevention.	Topical cream (e.g., clotrimazole, miconazole, ketoconazole, terbinafine if 12 years and older or tolnaftate, naftifine, or ciclopirox if 10 years and older) twice a day for 4–6 weeks. Do not use a topical corticosteroid to prevent a persistent or recurrent infection. Selenium sulfide shampoo 2 times a week on the child's body to help reduce the number of spores. Family members may also use the shampoo. An oral antifungal agent when no response to topical therapy.
TINEA CRURIS ("JOCK ITCH")	
Scaly, erythematous annular lesions on groin and upper thighs, may spread to the abdomen and buttocks; usually spares the penis and scrotum May have elevated lesions, papules, or vesicles	Topical antifungal agent (e.g., clotrimazole, miconazole, and terbinafine for ages 12 years and older, tolnaftate or ciclopirox for 10 years and older) for 4–6 weeks. Topical corticosteroids are not used. Wash body area with selenium sulfide shampoo. Wear loose clothing to promote dryness in the groin area.
TINEA PEDIS ("ATHLETE'S FOOT")	
Vesicles or erosions on instep or between toes (fissures, red scaly); dry scaly patches or plaques with erythema on plantar and lateral surfaces of foot Peeling maceration and fissures in lateral toe web spaces indicate secondary bacterial involvement Pruritus	Broad-spectrum topical antifungal agent with antibacterial properties (e.g., econazole or ciclopirox) Allow feet to air dry. Use 100% cotton socks, change twice daily; put socks on before other clothing to reduce transmission of fungus to groin.

The treatment of choice for most drug sensitivity reactions is discontinuation of the causative drug. In rare cases, a drug may be continued with careful monitoring when the child has a less severe sensitivity reaction because it is the best treatment choice. Supportive measures should be taken to decrease the intensity of the reaction. An antihistamine may be used to block the release of histamine, which causes the rash. Topical corticosteroids, cool compresses, and baths may also be prescribed for pruritus. For some severe drug reactions, the child must be hospitalized and treated on a burn unit.

TABLE 31–6 Clinical Manifestations of Drug Reactions

TYPE OF REACTION	CLINICAL MANIFESTATIONS
ALLERGIC DRUG REACTION	
Most commonly caused by sulfonamides, tetracyclines, NSAIDs, oral contraceptives, barbiturates, phenytoin, carbamazepine, benzodiazepines, and morphine	Erythematous, pruritic macules and papules; urticaria (hives) begins on the trunk and extends in a symmetric fashion, often sparing mucous membranes. Affected area darkens over 1–2 weeks, and skin peeling may occur. May heal with pigment changes.
ERYTHEMA MULTIFORME MINOR	
Hypersensitivity reaction to anticonvulsants, penicillins, salicylates, sulfa antibiotics, barbiturates, and phenytoin; infectious agents (e.g., herpes simplex virus)	Skin lesions may be preceded by fever, malaise, and upper respiratory symptoms. Widespread erythematous macules progress to target lesions (papules, vesicles, or bullae in a pale ring with an erythematous border). May progress to blisters and bullous lesions. Lesions may itch or burn. Lesions common on palms and soles, elbows, extensor surface of forearms and legs.
STEVENS–JOHNSON SYNDROME (SJS) AND TOXIC EPIDERMAL NECROLYSIS (TEN)	
Potentially life-threatening hypersensitivity reaction to penicillins, sulfonamides, cephalosporins, fluoroquinolones, antiepileptic medications, NSAIDs, acetaminophen, or reaction to infectious disease such as *Mycoplasma pneumoniae* Believed to be forms of the same disease and the most severe form of erythema multiforme.	Prodromal infection for 1–7 days with low-grade fever, sore throat, or malaise. Headache, muscle aches, joint pain, and vomiting and diarrhea may be seen. Erythematous skin is tender, progressing to blisters and bullae, and then to necrotic epidermis that sheds and weeps. Mucous membranes have blisters, erosions, ulcerations, and hemorrhagic crusting. Painful crusting and sloughing of the lips and oral membranes occur. Respiratory and gastrointestinal mucosa may also be affected. Erosions (similar to partial-thickness burns) may spread to cover up to 10% of the skin surface in SJS, 10%–30% in overlapping SJS and TEN, and more than 30% in TEN. Corneal blistering can lead to scarring and blindness.

Nursing Management

Teach parents to be alert for the signs of drug sensitivity reactions. Obtain a careful history of the child's past reactions to medications before starting new therapies. If a reaction occurs, discontinue the medication until the healthcare provider is notified. See the section on burns later in this chapter for nursing care for the child with a severe drug reaction.

SAFETY ALERT!

Children with a true drug allergy (having a past serious systemic reaction) should never be treated with that drug again. Prominently mark the child's records so that all allergies are easily identified. The child should wear some type of medical alert identification.

Chronic Skin Conditions

Atopic Dermatitis

Atopic dermatitis (eczema) is a chronic, relapsing, superficial inflammatory skin disorder characterized by intense pruritus (Figure 31–8). The condition affects approximately 20% of infants, children, and adolescents (Nicol & Huether, 2014). Up to 60% of children who develop the condition do so during the first year of life (Roduit et al., 2012). Most children have or develop allergic conditions such as asthma or food allergy.

Figure 31–8 Severe atopic dermatitis in an infant. Note the thick (i.e., lichenified), hyperpigmented plaque on the extensor surface of the elbow.

SOURCE: Courtesy of Daniel P. Krowchuk, MD, Professor of Pediatrics and Dermatology, Wake Forest School of Medicine, Winston-Salem, NC.

ETIOLOGY AND PATHOPHYSIOLOGY

It is believed that mutations in the *filaggrin* gene are associated with a defective skin barrier that allows epidermal water loss that leads to **xerosis**, generally dry skin that is likely to crack and fissure. This also permits the penetration of allergens, irritants, and organisms. Both an IgE-mediated immediate immune response and T-cell–mediated delayed immune response are involved. The inflammatory response with cytokines, T-lymphocytes, and other cells plus scratching further damages the skin barrier (Tom, 2012). Although food allergies often occur in children with atopic dermatitis, food allergies do not cause the condition (Tollefson, Bruckner, & Section on Dermatology, 2014).

Decreased recognition of pathogens by immune receptors and decreased response by neutrophils and natural killer cells after an infectious agent enters the skin leads to more skin infections, such as *Staphylococcus aureus*, which is colonized on the skin of 90% of affected children (Tollefson et al., 2014; Tom, 2012).

CLINICAL MANIFESTATIONS

Acute atopic dermatitis is characterized by patches with papules, vesicles, exudate, crusts, and excoriation. Some patches may weep. Chronic atopic dermatitis characteristics include darkened, thickened skin with prominent skin lines (lichenification), excoriation, dryness, and scaling. Inflammation usually occurs on the face, neck, and extensor surfaces in infants. The diaper area is usually spared in infants because the skin is damp and protected from scratching. The antecubital and popliteal skinfolds are often affected after age 2 years. Adolescents may additionally have these areas affected: the eyelids, where the earlobe touches the face, fingertips, toes, nipples, and the vulva.

The itching interferes with sleep and causes irritability. The child moves so much because of the itching discomfort that a perception of hyperactivity may occur. Erythema and warmth may indicate a secondary bacterial infection. Some children have repeated flares or chronic atopic dermatitis that persists into adulthood. Other children may have skin resolution when respiratory symptoms such as asthma develop.

CLINICAL THERAPY

Atopic dermatitis is distinguished by its history and clinical manifestations. Diagnostic features of atopic dermatitis include an early age of onset, parent or sibling with history of atopy, pruritus, dry skin, and the typical distribution of lesions for age, such as the cheeks, scalp, trunk, and extremities during infancy, the flexural areas during childhood, and the hands and feet during adolescence (Tollefson et al., 2014). No laboratory tests are diagnostic; however, children have an elevated IgE level. A skin culture may be obtained when secondary infection occurs.

Because there is no cure, the goals of treatment are to hydrate and lubricate the skin, reduce pruritus, minimize inflammatory responses, manage infectious triggers, and treat skin infections. The skin is hydrated by bathing, and then the entire body is lubricated by applying occlusive topical emollients within 3 minutes of leaving the water. This traps moisture in the skin and promotes flexibility of the skin without cracking.

Clinical Tip

Select fragrance-free emollients with a cream or ointment base that have the fewest preservatives. Lotions contain alcohol that will further dry the skin. Examples of emollients include Eucerin cream, Aveeno cream, Vanicream, Cetaphil cream, SBR-Lipocream, and petroleum jelly. Petroleum jelly (e.g., Vaseline) has the benefit of lower cost, especially since so much of the emollient must be used to cover the entire body each day.

Moisturizing ointments and creams are applied 3 to 4 times a day, or when the skin feels dry.

Topical corticosteroids reduce inflammation and achieve quick control. Ointments are preferred over creams because of their occlusive effect, which ensures a stronger barrier and absorption into the skin. Many different preparations and seven categories of corticosteroid strength exist. Moderate-strength corticosteroids are used twice daily for 2 weeks under the emollient. Low-strength corticosteroids are used for thinner skin areas, such as the face, diaper area, and skinfolds. When the inflammation resolves, topical corticosteroids are tapered in frequency of application and potency and then discontinued. To reduce the risk for steroid side effects, topical steroids are not used on healthy skin. Oral corticosteroids are not commonly used because of a rebound effect may occur in which a more severe rash returns after the medication is discontinued (Tollefson et al., 2014).

SAFETY ALERT!

The potency or strength of a topical corticosteroid is based on whether it is fluorinated and contains other ingredients. Refer to a drug manual to identify the corticosteroid potency, not the percentage listed on the medication label. Avoid the use of higher potency corticosteroids on the face, genitalia, and skinfolds where absorption of the medication is increased because of the thinness of the skin. Intraocular hypertension, cataracts, skin atrophy, and adrenal suppression are potential adverse effects of higher potency topical corticosteroids.

Immunomodulator ointments such as tacrolimus (Protopic) and pimecrolimus (Elidel) are increasingly used as a second-line treatment for some children. Disadvantages include the cost of these medications and burning with application as perceived by some children. The medications are approved by the U.S. Food and Drug Administration (FDA) for children over 2 years of age, for short-term or intermittent treatment, who are not responsive to conventional therapy. The FDA has placed a black box warning on both drugs because of rare cases of malignancy (Tom, 2012).

The *Staphylococcus aureus* colonization on the child's skin may trigger an immune cascade that increases pruritus. Topical, oral, or IV antibiotics may be selected depending on severity of infection. Cephalexin is a common oral antibiotic used to treat *S. aureus* when CA-MRSA is not involved. When the child's skin condition does not respond, a skin culture may be needed to identify the correct antibiotic. Superinfections with herpes simplex may be treated with oral or intravenous acyclovir, depending on the severity of the infection. Children may be encouraged to soak in a tub with dilute chlorine bleach (one half cup to a tub one quarter full) once or twice a week to help reduce the number of *S. aureus* bacteria on the skin (Tollefson et al., 2014).

Pruritus is a significant problem, and treatment of flare-ups is the best way to reduce itching. Oral antihistamines have a limited effect on itching, but the sedative effect may help promote sleep. Tolerance to the sedating effects of these medications occurs, so their use is limited to 2 to 7 nights during a flare-up, when scratching interferes with sleep. Topical antihistamines are not recommended because of the potential for hypersensitivity reactions and contact dermatitis. Environmental control may be helpful. A humidifier in the winter counteracts dryness of the surrounding air, minimizing loss of skin moisture. Air conditioning in the summer limits unnecessary sweating that can exacerbate inflamed areas.

Food allergies causing urticaria and pruritus may aggravate atopic dermatitis. When the child younger than age 5 years has atopic dermatitis that does not respond to optimal management, efforts may be made to identify specific allergies to foods such as

Clinical Reasoning **The Child With Atopic Dermatitis**

Noah, 15 months of age, has had atopic dermatitis since 6 months of age. Today, he has skin lesions on his face, neck, elbows, and knees. The patches on his elbows and knees are weeping, and he is very uncomfortable because of the itching. His mother has worked hard to treat his skin and is very frustrated at this latest flare-up. She has run out of the corticosteroid ointment.

When talking with Noah's mother, the nurse reviews the daily routine for his care and identifies some changes that may help reduce the number of flare-ups. The nurse recommends the following daily skin care routine: Let Noah soak for 10 to 15 minutes in a warm bath and use mild soap only on skin that is dirty. Pat dry and immediately put the corticosteroid ointment over skin lesions and then petroleum jelly over his entire body. Apply petroleum jelly or other moisturizer every morning to skin that is dry.

- What signs of infection should the nurse and mother be observing for?
- What information can you provide to Noah's mother regarding the role of food allergies in causing atopic dermatitis?
- Contrast the treatment of acute flare-ups with daily maintenance care for atopic dermatitis.

eggs, cow's milk, wheat, soy, and peanuts (Tollefson et al., 2014). See Chapter 14 for more information on food allergies and food elimination trials to identify food allergies.

Nursing Management

For the Child With Atopic Dermatitis

Nursing Assessment and Diagnosis

Take a thorough history, including any family history of allergy, environmental or dietary factors, past exacerbations, and what triggers a flare. For example, common triggers include harsh soaps and detergents, fragrances, rough nonbreathable clothing, sweat, and psychosocial stress. Note distribution and type of lesions, presence of weeping, or signs of infection.

Identify the impact that the skin disorder is having on the child and family. How much is the sleep of the child, siblings, or other family members disturbed? Is the child's self-esteem disturbed? What other stresses has the child's skin disorder placed on the family? Does the family have concerns about topical steroid medication use?

Common nursing diagnoses that may be appropriate for the child with atopic dermatitis include the following (NANDA-I © 2014):

- ***Tissue Integrity, Impaired,*** related to chemical irritants and mechanical factors (abrasive clothing)
- ***Insomnia*** related to prolonged physical discomfort (itching)
- ***Infection, Risk for,*** related to breaks in skin barrier
- ***Self-Esteem, Chronic Low,*** related to peer reaction to visible skin lesions
- ***Health Management, Family, Ineffective,*** related to excessive demands made on the family to keep the condition under control

Planning and Implementation

Nursing management focuses on education and emotional support. Atopic dermatitis can be controlled, but there is no cure. Advise parents that the lesions are not contagious and usually do not scar. Daily optimal management often reduces flares, but the time it takes is a family stressor. Emphasize the importance of following the daily treatment plan to promote healing of existing lesions and to reduce the risk of secondary infections. See *Families Want to Know: Atopic Dermatitis Daily Skin Care*. Help parents and adolescents deal with the frustration of the acute flare-ups of the condition by reinforcing that remissions do occur with good home care.

Clinical Tip

Daily application of emollients to the entire body of newborns with a parent or sibling with atopic dermatitis or atopic condition has been suggested as a strategy to postpone the onset of atopic dermatitis. A pilot study involving 124 families demonstrated reduced incidence in newborns with daily emollient treatment compared to babies with routine newborn skin care (Simpson et al., 2014). This may be a potential future strategy for newborns at high risk of atopic dermatitis.

The child, parents, and siblings are often tired because of lost sleep when the child scratches at night during an acute flare-up. School performance may be affected if the child has sleep deprivation or if the child is experiencing physical discomfort that interferes with learning. The itching and scratching may cause constant movement similar to attention-deficit hyperactivity. If an oral antihistamine has been ordered, make sure the parents understand when to give the medication to maximize its effectiveness for better sleep.

Atopic dermatitis produces visible changes that can affect a child's self-confidence and self-esteem. Identify activities that the child can participate in to improve self-esteem. Even though humidity and sweating can make eczema worse, encourage the child to participate in sports. The child should shower as soon as possible after strenuous activity and then apply needed medications and emollients.

Provide encouragement and positive reinforcement for improvements in the child's skin during healthcare visits. Ensure that a focus is on the child's health promotion during visits. See *Health Promotion: The Child With Atopic Dermatitis*. Encourage the parents to support the child's self-esteem. Atopic dermatitis is difficult to manage and may have a more profound effect on the child's and family's quality of life.

When atopic dermatitis is under control, educate parents that increased itching within hours of eating a food may be associated with a food allergy that aggravates atopic dermatitis. If a specific food allergy, such as eggs, has been identified, educate the parents about strategies for avoidance of food products that contain the allergen. Nutritional counseling may be needed to make sure the child has food options that meet daily nutritional requirements.

Evaluation

Expected outcomes of nursing care include the following:

- The child's atopic dermatitis is controlled and no infection occurs.
- Parents identify triggers of the child's atopic dermatitis and avoid or eliminate them.
- The child's sleep is minimally disturbed by itching.

Families Want to Know

Atopic Dermatitis Daily Skin Care

- Have the child soak in the bathtub 10–15 minutes or shower once a day. Use mild, unscented soap only on dirty areas. Salt or baking soda added to the bath water may help if water stings the child's open lesions. Rinse and pat excess water from the skin and apply adequate emollient to the entire body within 3 minutes to trap moisture in the skin.
- Help the parents select an unscented emollient ointment or cream (Eucerin, Aveeno, Vanicream, Cetaphil, SBR Lipocream, or petroleum jelly) that fits into the family's budget. Large quantities are needed to cover the entire body twice a day. Petroleum jelly is inexpensive, safe, and easily applied.
- In regions with low humidity, apply emollients to the skin more frequently.
- Help ensure that parents receive adequate amounts of topical corticosteroids for effective treatment of a flare-up. When the child has a flare-up, bathe the child twice a day and apply the topical medications on inflamed areas, spreading thinly and rubbing in. Emollients are applied on top of medications as well as over the rest of the body.
- If immunomodulators are prescribed rather than topical corticosteroids, spread a pea-size amount to cover a 2-in. (5-cm) circle over the inflamed area. Apply emollients as for topical corticosteroids.
- Encourage the child to wear loose cotton clothing rather than wool or other irritating fabrics.
- Keep the child's fingernails trimmed and use clean cotton gloves or socks over the infant's or child's hands to decrease scratching and reduce the chance of secondary infection.
- Contact the child's healthcare provider if signs of infection are noted so that antibiotic treatment can be started.

Health Promotion The Child With Atopic Dermatitis

Growth and Development Surveillance

- Assess growth measurements and plot on a growth chart. Identify any changes that could be related to an altered meal plan due to food allergies.
- Assess developmental progress for age.

Nutrition

- Postpone adding eggs to the infant's diet if atopic dermatitis develops early in infancy. Provide nutritional counseling to ensure the child gets all essential nutrients when foods must be avoided.

Physical Activity

- Encourage physical activity, but have the child bathe and apply emollients soon afterwards.
- After swimming have the child immediately rinse off chlorine after leaving the pool and apply emollients.

Family Interactions

- Identify how frequently the sleep of the child and other family members is disturbed by scratching. Encourage the use of an antihistamine to promote sleep when a skin flare-up occurs.
- Discuss strategies to effectively use time for daily skin care.

Mental and Spiritual Health

- Assess the child's self-esteem and impact of skin lesions on relationships with peers.
- Identify how disturbed sleep affects behavior and learning.

Disease Prevention Strategies

- Provide all immunizations on schedule.
- Encourage good hand hygiene to reduce the risk of infection.
- Educate the child and parents to provide skin care as described in *Families Want to Know: Atopic Dermatitis Daily Skin Care* to reduce skin inflammation and the risk for secondary infection.

Acne

Acne is a chronic inflammatory disorder of the pilosebaceous hair follicles on the face and trunk. It is the most common skin disorder in the pediatric population, affecting 85% of the population ages 12 to 25 years (Nicol & Huether, 2014). Acne is found in all ethnic groups, and occurs equally in male and female adolescents. Severe acne is more common in male adolescents. Adolescents with severe acne often have a genetic predisposition.

ETIOLOGY AND PATHOPHYSIOLOGY

Keratin and sebum usually flow to the skin surface through the hair follicles. Androgens, released as puberty begins, trigger the sebaceous glands to increase the production of sebum. When the extra sebum mixes with the keratinocytes and causes them to clump together, the hair follicle canal becomes obstructed by **comedones** (whiteheads and blackheads). The sebum behind the comedone is an ideal environment for the anaerobic bacterium *Propionibacterium acnes*, which metabolizes the sebum, leading to an increased response by inflammatory mediators (Kim & Mancini, 2013). When the inflammatory reaction is close to the surface, a papule or pustule develops. If the inflammatory reaction is deeper, a larger papule or nodule develops. When the follicles rupture, bacteria spreads and the resulting inflammation in the deeper tissues leads to nodules and cysts that can result in scars.

Acne may occur in neonates in response to maternal androgen hormones and androgens produced by the fetal adrenal glands. Neonatal acne usually resolves spontaneously in a few months. When acne occurs in children between 1 and 7 years, it may be associated with true precocious puberty or an androgen-secreting tumor (Kim & Mancini, 2013).

CLINICAL MANIFESTATIONS

Lesions occur most often on the face, upper chest, shoulders, and back. Comedones are initial skin lesions. Closed comedones are whiteheads or flesh-colored papules with tiny follicular openings. Open comedones are blackheads in which the follicular plug has enlarged and dilated the follicular opening. As inflammation occurs, papules and pustules develop (Figure 31–9). Nodules are larger areas of inflammation that may involve more than one hair follicle. Cysts are compressible nodules without overlying inflammation. Scars form when the surrounding dermis is damaged and may be pitted, atrophic, or hypertrophic (keloid).

CLINICAL THERAPY

Diagnosis is based on the examination of the skin. Treatment is customized to the predominant type of lesion present and severity of the lesions. The goal of treatment is to suppress lesions until the condition is outgrown, thus preventing infection and scarring, and minimizing psychologic distress. A variety of topical and oral medications are prescribed (see *Medications Used to Treat: Acne*). Acne will recur gradually if the treatment is stopped, so maintenance therapy with topical retinoids is recommended once acne is controlled.

Skin irritation related to topical preparations may occur in adolescents with sensitive skin. Using a lower-concentration product and removing it after a few hours may reduce the initial irritation. With continued use the skin adapts, permitting the product concentration to be changed. Creams are used when skin is more sensitive, and gels are used when skin is oilier. (See *Developing Cultural Competence: Acne Lesions in Individuals With Dark Skin*.)

Isotretinoin (Accutane) is reserved for severe acne that is not responsive to other therapies. The daily 16- to 20-week course of treatment results in a dramatic improvement for up to 90% of patients (Studor-Heikenfeld & Colella, 2014). An intermittent lower-dose schedule over 6 to 18 months is also effective and has fewer side effects. Because isotretinoin is a teratogen, the FDA established the iPLEDGE program, a mandatory Internet-based registry for prescribers, patients, and pharmacies. See *Medications Used to Treat: Acne* for important guidelines. Inquire about prior episodes of depression and suicide attempts because of isotretinoin's potential association with both problems.

Figure 31–9 **Note the comedones, papules, pustules, and healing lesions. Acne can have a significant effect on an adolescent's self-esteem.**

SOURCE: bluecinema/Getty Images.

Developing Cultural Competence Acne Lesions in Individuals With Dark Skin

Inflammatory acne in adolescents with darker skin color is associated with a dark discoloration as extra pigment gets deposited in the areas of inflammation. If protected from sun exposure, this darker coloration fades over 3 to 18 months. Encourage adolescents with dark skin to use noncomedonic sunscreen (SPF 30 or higher) whenever sun exposure is likely.

Nursing Management

For the Child With Acne

Nursing Assessment and Diagnosis

Physical assessment should include documentation regarding distribution, type, and severity of acne lesions. Assess the adolescent's and parents' knowledge about the cause and treatment of acne. Also explore the extent of emotional distress and low self-esteem that acne may be causing.

The accompanying *Nursing Care Plan: The Adolescent With Acne* lists common nursing diagnoses and summarizes nursing care.

Planning and Implementation

Nursing management focuses on educating the adolescent and parents about acne and its treatment. Encourage good hand hygiene before touching affected areas. Educate adolescents that picking and squeezing lesions may increase the inflammation when lesions rupture below the skin surface and may cause scarring. Excoriated acne lesions do not respond as well to the treatment used for the primary acne lesions. Inform the adolescent to avoid cleansing products with a greasy base, to shampoo the hair regularly, and to treat seborrheic dermatitis that can accompany acne. Correct misconceptions about dietary causes. Although no food is known to cause acne or increase the severity of lesions, good nutrition is important.

Topical medications should be spread in a thin film over the skin, according to directions. Inform the adolescent that treatment may seem to worsen acne as the comedones are being pushed out, and this is a sign that the medication is working. Emphasize that treatment is often long term. It may take at least 6 to 12 weeks for significant improvement to be seen after beginning treatment. Educate adolescents that healing lesions initially look like fading red areas, and, in some cases, hyperpigmented areas. Flare-ups are expected despite treatment, potentially caused by increased sweating, heat, humidity, and emotional stress.

Tretinoin is **phototoxic** (a rapid nonimmunologic reaction of the skin when exposed to sunlight), causing sunburn with even minimal exposure. Encourage adolescents to limit sun exposure

(*continued on p. 920*)

Medications Used to Treat: Acne

MEDICATION AND ACTION	NURSING MANAGEMENT
Topical retinoids (tretinoin [Retin-A], adapalene, tazarotene) For mild or moderate papulopustular acne Regulates follicular keratinocyte shedding, has anti-inflammatory properties, helps to prevent new lesions, enhances penetration of topical antibiotics	• Use lower concentrations initially as skin irritation is common. • Divide and spread a pea-sized amount over the entire face. Do not use as spot therapy. • Apply at night to reduce photosensitivity effect. • Use long term between flares for maintenance.
Benzoyl peroxide For mild or moderate papulopustular acne Topical antimicrobial with bacteriocidal action	• A lower strength may be used initially if skin irritation occurs. • Apply in the morning. • Inform clients that the product can bleach fabric.
Antibiotics (tetracycline, minocycline, erythromycin, doxycycline) Topical for mild inflammatory acne; oral for moderate to severe inflammatory acne Antimicrobial action reduces resident skin bacterial colonization	• Combined with topical retinoid and benzoyl peroxide to reduce antibiotic resistance. • Takes 6–8 weeks to see improvement; antibiotic is changed if no response. Use is evaluated after 3 months to determine need for longer treatment. Avoid long-term use to reduce risk for antibiotic resistance.
Azelaic acid For mild or moderate papulopustular acne Keratolytic and anti-inflammatory properties	• Used in patients who cannot tolerate topical retinoids. • Apply twice daily.
Isotretinoin (Accutane) For severe nodular acne, especially when resistant to other treatment Causes sebaceous gland atrophy and decreases sebum production; reduces excess desquamation, bacteriocidal action, reduces inflammatory response, reverses effect of androgens on sebaceous glands	• Requires informed consent. • Females need a monthly pregnancy test before each prescription refill as well as monthly tests for blood counts, lipid levels, and liver enzymes. • Females must use 2 forms of contraception, beginning 1 month prior to treatment, during treatment, and for 1 month after completing treatment to prevent pregnancy that would expose the fetus to teratogenic effects of the drug. • Take medication with food to increase oral absorption. • Encourage the use of sunscreen and protective clothing to prevent sunburn.
Oral contraceptives For persistent inflammatory papules and nodules Suppresses gonadotropin secretion and reduces ovarian androgen production	• Use as an adjunct to other acne treatments. • May cause red, dry, and itching skin that can be treated with emollients. • Inform adolescent that acne may worsen during the first 3–6 weeks of treatment.
Spironolactone For severe acne. Blocks the androgen receptor on the sebaceous gland	• Prescribed for 1–3 months along with an antibiotic. • Not FDA approved for acne treatment, but commonly prescribed for that purpose.

Nursing Care Plan: The Adolescent With Acne

1. Nursing Diagnosis: *Health Maintenance, Ineffective,* related to daily hygiene and skin care (NANDA-I © 2014)

GOAL: The adolescent will verbalize proper hygiene, nutrition, and treatment of acne.

INTERVENTION	RATIONALE

• Teach good skin care:
  • Wash skin with mild soap and water twice a day.
  • Do not use astringents or abrasive cleansers.
  • Wash hands frequently, especially after eating greasy foods.
  • Apply topical retinoid 20 min after washing and drying face.
	• Good hygiene and appropriate skin care reduces irritation, surface oils, and bacteria, which intensify inflammatory reactions. Astringents and aftershave may contain alcohol and further dry the skin.

• Praise good habits.	• Positive reinforcement encourages continued effort.
• Advise the adolescent to wash hair with antiseborrheic shampoo and to avoid oil-based cosmetics, pomades, or petroleum-based hair products.	• Seborrhea frequently accompanies acne. Oil-based products can obstruct sebaceous glands, exacerbating acne.
• Encourage the adolescent to keep a diary of skin care, menses, and diet habits.	• A record may help identify associations with flares that can be managed in the future.

EXPECTED OUTCOME: Adolescent will exhibit good hygiene habits and nutrition.

GOAL: The adolescent will verbalize understanding of treatment regimen.

INTERVENTION	RATIONALE
• Educate the adolescent about medications (action, side effects, dosage, method of application).	• Proper application of medication enhances healing of lesions.
• Encourage application of tretinoin at night. Encourage use of noncomedonic sunscreens of at least SPF 30 during the day.	• Nighttime application helps reduce sensitivity to sun and sunscreen helps to avoid sunburn.
• Educate the adolescent about time needed for a therapeutic response and importance of adhering to daily regimen.	• Up to 3 months may be needed for significant improvement. The adolescent needs a reason to continue with the care plan.
• Encourage continuation of daily therapies even when acne has improved significantly.	• Acne will return if treatment stops.

EXPECTED OUTCOME: Adolescent will implement the treatment regimen as outlined, resulting in a noticeable reduction in lesions.

2. Nursing Diagnosis: *Body Image, Disturbed,* related to biophysical factors (visible facial lesions) (NANDA-I © 2014)

GOAL: The adolescent will demonstrate increased self-confidence and self-esteem.

INTERVENTION	RATIONALE
• Establish a rapport with the adolescent.	• A trusting relationship promotes verbalization of concerns and fears.
• Provide education about the condition and therapy modalities.	• Providing information better enables the adolescent to take control of the condition.
• Encourage the adolescent to be responsible for treatment and follow-up, and give positive reinforcement.	• Responsibility reinforces sense of self-esteem.
• Encourage the adolescent to become involved with school activities and peers.	• Involvement in activities helps enhance self-esteem and allows the adolescent to explore new experiences and friendships.

EXPECTED OUTCOME: Adolescent will freely discuss concerns and fears. Adolescent will demonstrate active involvement in own care. Adolescent will show increased confidence, as demonstrated by involvement in extracurricular activities.

and to use noncomedonic sunscreen products. Review instructions for taking other prescribed drugs, such as tetracycline and isotretinoin (Accutane), and discuss possible side effects. Emphasize the importance of return visits to the adolescent's healthcare provider to monitor medication side effects.

Psychologic support is an important aspect of care. Because adolescents are preoccupied with their body image and peer relationships, they often find having acne embarrassing. Monitor for signs of anxiety or depression. Encourage them to express their feelings and refer for counseling, if necessary.

Evaluation

Expected outcomes of nursing care can be found in *Nursing Care Plan: The Adolescent With Acne.*

Psoriasis

Psoriasis is a chronic, relapsing, pruritic, papulosquamous condition that affects the skin, scalp, and nails. It begins during childhood or adolescence in a third of cases (Bhutani, Kamangar, & Cordoro, 2012). A family history of psoriasis is often present, but a multifactorial inheritance is suspected.

Psoriasis is a T-helper cell–mediated autoimmune disease. Inflammatory cytokines from activated T cells cause chronic inflammation and are responsible for the skin changes (McCann & Huether, 2014). Cells proliferate so rapidly they do not mature and fully keratinize, leading to thickened epidermis and plaque formation. The onset of psoriasis may be triggered in children, particularly guttate-type psoriasis, by a streptococcal infection. Other triggers may include trauma, stress, and recent withdrawal from oral corticosteroids (Bhutani et al., 2012).

The typical psoriatic lesion is a thick, silvery, scaly erythematous plaque with an irregular border, surrounded by normal skin. Pruritus is often present. These lesions commonly are found on the scalp, elbows, knees, umbilicus, and genitals, or at the site of trauma. Nails may also be involved. Small points of bleeding may be noted when a scale is removed. Guttate psoriasis is characterized by an eruption of small round or oval papules on the trunk, face, and extremities. Some children also develop psoriatic arthritis.

Diagnosis is based on skin lesion characteristics or microscopic examination. Treatment includes topical steroids twice a day. Care must be taken to use lower-potency steroids in the diaper area and the face, and to switch from higher-potency to lower-potency steroids when lesions thin. Other topical medications include vitamin D, a retinoid, and tacrolimus or pimecrolimus. A tar shampoo may be used to clear scales in the scalp prior to topical steroid application. Salicylic acid may be used to remove some layers of plaques. Ultraviolet B phototherapy is used for children who do not respond to topical therapy. Systemic therapy with drugs such as methotrexate, oral retinoids, and cyclosporine is reserved for children with severe psoriasis. No cure exists, and lifelong relapses and remissions occur.

Nursing Management

Assess the child's skin for extent of the lesions and response to therapy. Spend time talking with the child and family to learn how the condition affects them. Educate them about the condition and reasonable expectations related to treatment. Families need to understand that lesions are not contagious, and periods of remissions and flare-ups are common. Actively involve the family and child in decision making regarding the treatment plan, such as the type of topical products (e.g., lotion, cream, ointment) they prefer to use. Teach them how to apply topical medications. Encourage the child to avoid situations in which chemical and physical trauma to the skin could occur.

Children and adolescents may have feelings of embarrassment, anger, and frustration related to their visible skin lesions. Psoriasis may impact their daily lives causing problems at school, with personal relationships, and with social acceptance. Children may anticipate rejection and withdraw from physical activities that require them to expose affected skin areas, such as swimming. The mental health of adolescents should be monitored to identify psychologic distress, depression, or substance abuse.

Epidermolysis Bullosa

Epidermolysis bullosa (EB) is a rare and severe chronic blistering skin disorder that occurs with minor trauma. EB is most often inherited in an autosomal dominant pattern (see Chapter 3). The incidence of the most common and least severe form, EB simplex (EBS), is estimated to be 1 per 25,000 live births (Coulombe & Lee, 2012).

Genetic changes in the intracellular proteins compromise their ability to provide structural support in keratinocytes of the epidermis. The basal keratinocytes are fragile and rupture easily with any mechanical injury trauma. One variant of EBS is localized to blistering of the hands, and another variant leads to more generalized blistering. It is often diagnosed when the child begins to walk or during puberty. With severe forms of EB, blistering and skin erosions are seen at birth and occur on all parts of the body, including the respiratory, gastrointestinal, and urologic systems. These children lose protein and have electrolyte and fluid imbalances, malnutrition, and anemia. Severe EB has a high mortality rate due to secondary infection.

Children with EB have extremely fragile skin, and blisters form with minor trauma, friction, or heat applied to the skin. In severe forms, the blistering can be extensive and damage to the skin is apparent. Fingers and toes may fuse with healing, leading to malformations. Children experience pain with blisters and may have difficulty walking when feet are affected. In the more common form of EB, blisters generally heal without scarring.

Diagnosis can be made prenatally by amniocentesis or chorionic villus sampling or by skin biopsy. The condition is managed by prevention of new blisters, wound care, good nutrition, and minimizing the risk for infection. Wound care is important to reduce the risk of infection. Blisters are pricked on two sides with a sterile needle each day and drained so that they do not extend. The blister roof is kept intact to act as a natural biologic dressing. Antibiotic ointments are applied to wounds, and changed monthly to reduce the risk for bacterial resistance. Wounds are covered, and care is taken to avoid placing adhesives directly on the skin. Biologic dressings may be used to cover larger wounds in some cases. Infants and children need additional protein and calories to support chronic wound healing. Pain management is customized to the severity of the child's condition and wound care provided.

Nursing Management

Teach the family to provide daily wound care at home. Wound care can be quite time consuming, so help the parents select the best time to do routine dressing changes. Perform dressing changes in a location without air currents to reduce pain from exposed wounds. Determine if financial support is needed to ensure that parents have the dressing supplies needed to

effectively manage the child's wounds. Provide parents with guidance on all aspects of dressing changes.

- Precut dressings to reduce the wound exposure time.
- Gather all supplies and have an assistant present. Ask the assistant to gently hold the child's extremities to prevent movement of the extremity during blister lancing and dressing changes. Holding or grabbing the extremity too tightly can cause friction injury.
- Use soft music and distraction to help calm the infant.
- Soak off dressings that are stuck to the skin. Remove dressings from one area at a time as air exposure may cause pain.
- Inspect the skin each day for signs of infection.
- Use nonadherent dressings that can absorb the blister fluid to help prevent dressings from sticking to the skin. Place a bulky cover over the dressing to protect the skin and promote healing. Wrap fingers and toes separately so they do not fuse together with healing.

Help the parents identify ways to protect the skin but still permit the child to interact with other children and have opportunities for development. Dress the child in soft cotton clothing that covers the skin, placing rough seams that can irritate the skin on the outside. Foam padding can be sewn into clothing over the knees and elbows for the infant who is crawling or walking. Shoes without seams on the inside should be worn with seamless cotton socks. Cotton socks can be used to mitten the infant's hands during sleep. The child should also avoid sun exposure and stay where temperatures are cool.

Because protein is lost with blisters, and chronic wound healing requires extra calories, it is important to promote good nutrition with adequate calories and high protein to meet the child's growth and healing requirements. In infants, blistering in the mouth may interfere with feeding. A soft nipple with a larger hole may be easier for the infant to use. Vaseline on the lips may help reduce trauma to the mouth. Food temperature should be cool or room temperature and nonacidic to prevent injury to the gastrointestinal tract. In some cases, a gastrostomy tube is inserted for nutritional supplementation. Regularly measure height and weight and plot measurements on a growth curve to monitor growth and to identify growth deficiencies early.

Help parents and the child manage the psychologic impact of this disfiguring disorder and the inability to fully participate in all activities. An individualized health plan with educational accommodations will be necessary. Because the hands and feet are often involved, writing and test taking may be challenging. Mobility and walking throughout the school may also be a problem. Information needs to be provided to classroom teachers and classmates to help minimize injury.

Infestations

Pediculosis Capitis (Lice)

Pediculosis capitis is a lice infestation of the hair and scalp. Infestation occurs among children from all socioeconomic levels, and it is most common in children ages 3 to 11 years (Eisenhower & Farrington, 2012). Parents or teachers may be the first to notice lice, or healthcare providers may spot them during routine examination (see Chapter 5). Outbreaks occur periodically among children in child care and elementary school.

Head lice live and reproduce only on humans and are transmitted by direct hair-to-hair contact or indirect contact such as sharing of hair accessories, hats, towels, and bedding. Lice do not fly or jump, but they can crawl quickly. The female louse can lay up to 10 eggs (nits) a day on the hair shaft, close to the scalp. The incubation period for eggs to hatch is 7 to 10 days. Lice feed on human blood, sensitizing the child with their saliva to cause pruritus.

Figure 31–10 **Note the presence of lice (highly magnified) crawling through the hair.**

SOURCE: Darlyne A. Marawski/National Geographic Image Collection.

The child has intense pruritus and complaints of "dandruff" that sticks to the hair (actually the nits) and "bugs" in the hair. Nits look like silvery white, yellow, or darker 1-mm teardrops adhering to one side of the hair shaft, often near the scalp. Lice are wingless insects (2 to 3 mm long) that move away from light and are not easily seen (Figure 31–10). Scratching may lead to inflammation, pustules, and bacterial infection. Occipital and posterior cervical nodes are frequently palpable.

Treatment involves a pediculicide shampoo, such as pyrethrin within an enzymatic lice egg remover, or an ovicidal rinse, such as permethrin (Nix); however, resistance to these products has increased. Permethrin cream rinse is applied to dry hair and left in place for 10 minutes, before rinsing. The hair is towel-dried, and the nits are removed with a fine-toothed comb. A second treatment is needed in 7 to 10 days because the neurotoxin is not effective on nits. If live lice still persist after two treatments, a prescription ovicide such as malathion may be ordered. Some newer agents are available. See *Medications Used to Treat: Head Lice.*

SAFETY ALERT!

Lindane is no longer recommended for treatment of head lice. However, it is still classified as a second-line treatment for head lice. It must be used with caution in any child weighing less than 50 kg (110 lb) because of neurotoxicity and potential to cause seizures. High levels of resistance by lice have been documented (AAP, 2015, p. 600).

Nursing Management

Carefully assess children exposed to head lice using a bright light and magnifying glass to look for lice and nits along the hair shaft close to the scalp. To avoid potential infestation, change gloves with each child when assessing several children in a classroom setting.

Infestation with lice can be upsetting for both the child and family. Emphasize to the family that anyone can get lice. All

Medications Used to Treat: Head Lice

NAME OF MEDICATION/PREPARATION	NURSING MANAGEMENT
First-line pesticide treatment	
Permethrin 1% Crème Rinse—Nix	• Apply to the hair after shampooing and towel drying the hair. Leave on 10 min and rinse. Repeat in 7–10 days.
Pyrethrin shampoo (0.33%) or piperonyl butoxide (Rid, A-200, Bayer, and generic brands)	• Apply to *dry hair and scalp*. Lather, leave on 10 min, and rinse with cool water. Wet hair dilutes the product and may contribute to treatment failure. • Permethrin is approved for children 2 months of age and older.
Benzyl alcohol 5% (Ulesfia)—FDA-approved nonneurotoxic treatment for children ages 6 months and older; lice die by suffocation	• Apply to *dry hair*, saturating the hair and scalp. Rinse after 10 min. Repeat in 7 days. Protect eyes during use. Available by prescription.
Spinosad (Natroba)—FDA-approved for children 4 years and older; lice become paralyzed and die, ovicidal	• Apply topical suspension to *dry hair*, saturating the scalp and all hair. Rinse off after 10 min. May repeat in 7 days. Available by prescription and is expensive.
Sklice—FDA-approved 0.5% ivermectin lotion for children ages 6 months and older	• Apply to *dry hair*, completely covering the scalp and all hair. Leave on 10 min and rinse only with water; *do not* shampoo. No retreatment needed in most cases.
Second-line pesticide treatment	
Malathion 0.5%—Ovide lotion	• Apply to *dry hair*. Leave on 4 minutes and rinse. No retreatment is needed. May cause stinging sensation. Has potential to cause chemical burns. • Treatment is flammable; do not expose the child to electric heat sources.

Source: Data from Eisenhower, C., & Farrington, E. A., (2012). Advances in the treatment of head lice in pediatrics. *Journal of Pediatric Health Care, 26*(6), 451–461; Pariser, D. M., Meinking, T. L., Bell, M., & Ryan, W. G. (2012). Topical 0.5% Ivermectin lotion for treatment of head lice. *New England Journal of Medicine, 367*(18), 1687–1693; Bowden, V. R. (2012). Losing the louse: How to manage this common infestation in children. *Pediatric Nursing, 38*(5), 253–254, 277.

family members and contacts of the child should be examined for infestation and treated as necessary. Teach the child not to share clothing, headwear, or combs.

Explain to parents that the shampoo and rinses prescribed are pesticides and must be used for the time specified and as directed. An extra bottle of the product may be needed if the child has extra-long hair. Inform parents that in order to avoid treatment failure no other shampoo or conditioner should be used before the lice shampoo or lotion. Do not wash the hair for 1 to 2 days after the pediculicide treatment. Keep these products out of the eyes and mouth of the child because they will irritate mucous membranes.

To remove nits, use a fine-toothed comb, tweezers, and a basin filled with water or isopropyl alcohol to dip and clean the comb and tweezers. Comb 1-inch sections from the scalp outward and pin these out of the way when done. Nits adhere to the hair shaft and must be manually pulled down the shaft with the comb, tweezers, or fingernails. All nits should be removed. Have blunt-nosed scissors available to cut a hair below the level of the nit when the nit cannot be removed. Put the child under a bright light and use distractions such as a video to keep the child entertained during the procedure. Check the hair every 2 to 3 days and remove any lice or nits seen. Giving boys a buzz haircut is one alternative. A shorter hair cut for girls may help with nit removal. Both the American Academy of Pediatrics and the National Association of School Nurses have policies that allow the child to stay in school even if all nits have not been removed.

Lice survive only about 3 days away from a human host, but nits may hatch after 8 to 10 days. For this reason, the child's bedding, towels, and clothing should be changed daily, laundered in hot water with detergent, and dried in a hot dryer for 20 minutes. Store nonessential bedding and clothing in a tightly sealed bag for 2 to 3 weeks and then wash. Discard hair accessories, brushes, and combs or soak them in hot soapy water (54.4°C [130.0°F]) for 10 minutes. Vacuum furniture and carpets and treat them with a hot iron when possible. Use of an insecticide in the home to kill the lice on carpets, furniture, and other items is not recommended when young children and pets may be exposed. Seal toys and other personal items that cannot be washed or dry-cleaned in a plastic bag for 2 weeks.

Scabies

Scabies is a highly contagious infestation caused by the mite *Sarcoptes scabiei*. It is spread by skin-to-skin and sexual contact. Transmission within a household is common. Children of all ages and both sexes can be affected. Because the mite usually takes at least 45 minutes to burrow into the skin, transient contact is unlikely to cause infestation.

The female mite burrows into the outer layer of the epidermis (stratum corneum) to lay her eggs, leaving a trail of debris and feces under the skin. The larvae hatch in approximately 3 to 4 days and proceed toward the surface of the skin. The cycle is repeated 14 to 17 days later. A delayed type IV hypersensitivity reaction to the mites, debris, and feces occurs within

4 weeks of infestation, causing irritation and intense pruritus (Cohen, 2014). Hypersensitivity response to reinfestation can occur within 24 hours.

Symptoms include a rash with papules and pustules, restlessness, and severe pruritus that worsens at night. Lesions may appear as linear, threadlike, grayish burrows 1 to 10 cm (0.4 to 4.0 in.) in length, which may end in a pinpoint vesicle. Lesions are usually located in the webs of the fingers, in the intergluteal folds, around the axillae, or on the palms, wrists, head, neck, legs, buttocks, chest, abdomen, and waist. In children under age 2 years, the head, neck, face, palms, and feet can be affected. The child's scratching and secondary infection often obliterate the linear burrow lesions. Nodules 2 to 20 mm (0.08 to 0.6 in.) in size occasionally develop as a granulomatous response to the dead mite antigens and feces and can persist for weeks after effective treatment.

Diagnosis is confirmed by microscopic examination of scrapings from a burrow, which reveals actively moving mites, fecal pellets, eggs, or nits. Treatment involves application of a scabicide, such as 5% permethrin lotion, over the entire body except the face, with special attention to the hands, fingers, feet, toes, and skin under the nails. Application of 5% permethrin lotion or malathion is preceded by a warm soap-and-water bath. When the skin is cool and dry, apply the lotion. The lotion is left in place for 8 to 48 hours before washing off. A second treatment is used 1 week later. Treat all members of the household and childcare contacts at the same time, even if they have no symptoms.

An oral antihistamine (e.g., Benadryl, Atarax) may be prescribed to help relieve itching. Antibiotics may be needed when a secondary infection occurs. Oral ivermectin, a new antiparasitic product with FDA approval for children weighing more than 15 kg, may be prescribed when treatment failure occurs.

Nursing Management

Advise parents that scabies is transmitted by close contact and is very contagious. All clothing, bedding, and pillowcases used by the child should be changed daily, washed with hot water, and ironed before reuse. Nonwashable toys and other items should be sealed in plastic bags for 5 to 7 days.

Educate the parents about the proper application of the scabicide. The child should have the scabicide reapplied to the hands if hands are washed or the child sucks the fingers or thumb. Socks over the young child's hands may reduce ingestion of the scabicide.

Treat all household members simultaneously. Uninfested individuals should avoid touching the affected child until after treatment is completed. If contact is made, they should wash their hands well. Inform the parents about signs of secondary infections and that itching and nodules may persist for weeks after effective treatment. Encourage the use of emollients because the treatment dries the skin.

Scabies, like pediculosis, can be embarrassing or upsetting for the child and family. Educate the child and parents about the condition, its spread, and treatment measures to prevent recurrence.

Vascular Tumors (Hemangiomas)

Vascular tumors, or hemangiomas, occur in 4% to 5% of infants (Lauren & Garzon, 2012). An increased incidence has been noted in female infants who are non-Hispanic, White, low birth weight, and of multiple births (Chung & Cohen, 2014). An increased incidence is found in infants with fetal exposure to chorionic villus sampling, placental complications, or preeclampsia (Uihlein, Liang, & Mulliken, 2012).

Hemangiomas are vascular tumors believed to result from the proliferation of endothelium-like cells that could be caused by a mutation and some type of environmental exposure. These tumors undergo rapid growth and attain 80% of full size by age 3 months, and most growth will be completed by age 5 months (Chung & Cohen, 2014). This phase is followed by a slow **involution** (process of decreasing in size) phase that may take years. Hemangiomas may be superficial (in the epidermis), deep (in the dermis or subcutaneous tissue), or mixed superficial and deep. When multiple hemangiomas are found, some may be in major organs, such as the liver. Complications caused by the rapid growth pressure against or obstruction of vital structures (e.g., airway, eye, or ear canal) may occur.

Infantile hemangiomas begin as barely visible **telangiectasias** (dilated superficial blood vessels) or red macules that begin to grow rapidly and become bright red and compressible. Some lesions ulcerate with rapid growth. Superficial hemangiomas are bright-red vascular cutaneous plaques that resemble strawberries. Deep hemangiomas appear as bluish tumors covered with normal-appearing epidermis. Mixed hemangiomas have features of both superficial and deep tumors. The lesions, appearing any place on the body, are minimally compressible and have no bruit or thrill. As the vascular tumor involutes, signs of tissue atrophy, wrinkles, telangiectasias, and hypopigmentation may be noted.

Initial diagnosis is by physical examination and monitoring the growth of the vascular tumor. When a vital organ could become obstructed or a large facial hemangioma is present, ultrasound, computed tomography, or magnetic resonance imaging may be performed.

Simple hemangiomas are monitored and receive no treatment. Hemangiomas in problem areas may be treated with oral propranolol at 1 mg/kg twice daily. Vital signs are checked prior to first dose and at 1 and 2 hours after the first dose. The child is checked again at 1 week and then monthly with vital signs being checked each visit. If the child has cardiovascular, respiratory, or endocrine conditions, or hemangioma in a vital organ, the child may be admitted for initial propranolol dosing because of potential adverse effects. The medication may be stopped temporarily if the infant has wheezing or severe cough because it may worsen wheezing associated with asthma (Block & Blackmon, 2013). Photos are taken of lesions at each visit to document changes in the lesion.

Pulsed-dye laser treatment may be used after involution for residual telangiectasia. Light energy pulses target the lesion's oxyhemoglobin, which is heated after absorbing the wavelength of light. This ruptures the lesion's blood vessels. Provide topical anesthesia and eye protection. The lesion may darken for 1 to 2 weeks, as red blood cells are released from ruptured blood vessels. The treated skin surface eventually lightens. Surgical removal of ulcerated hemangiomatous tissue may be considered if a poor cosmetic outcome is expected.

Nursing Management

Assess the distribution of the hemangioma and consider the potential for complications as it goes through a rapid growth stage, such as potential compression of the airway for a hemangioma in the neck area. Monitor the child for signs of any complications, such as ulceration. Assess the parents' response to the infant's appearance and how they are managing interactions with friends and family about the infant's changing appearance.

Take photos of the infant at each visit so that parents have a record of improvements once therapy is initiated.

Educate the parents about the type of vascular lesion and the time when growth is most rapid. Inform parents about the possible ulceration, if a hemangioma is rapidly growing, and what signs to expect. Parents should return for care when concerned about the lesion, if watchful waiting has been selected.

When propranolol medication is administered in the outpatient setting, monitor the pulse and blood pressure as directed for the first dose to detect adverse effects such as hypotension, bradycardia, or arrhythmia. Vital signs are taken on each subsequent visit. Educate the parents that propranolol should be given with or after meals to prevent hypoglycemia. Inform parents about the need to wake the infant to feed once or twice during the night to prevent hypoglycemia. Educate them about the signs of hypoglycemia to watch for and if seen to feed the infant before the blood sugar drops lower. Other adverse effects include restless sleep, cold extremities, and delayed capillary refill time.

Talk with parents about comments people make about the infant's appearance and provide some possible responses that parents can make. To promote attachment, help the parents see the infant's positive characteristics, such as responsiveness and smiling. Show photos of other children with similar lesions who have completed therapy to show that improvements in appearance are gradual, but possible.

Prepare parents for the changes in the child's appearance with pulsed-dye laser therapy. Some swelling may occur after the treatment, so the application of ice packs for 10 minutes every hour during the first day may help. Teach parents to protect the skin surface from trauma after pulsed-dye laser treatments and to keep the infant's nails short to prevent scratching. Cleanse the area treated with water and pat it dry. Inform parents to avoid sun exposure for several weeks after the treatments, and to use sunscreen in the future.

Injuries to the Skin

Pressure Ulcers

Many children with disabilities are cared for in hospital, community, and home care settings, and they are at risk for skin breakdown and pressure ulcers. Children at greatest risk are those with limited mobility, the inability to change positions, sensory deficits, or incontinence. Infants and children at higher risk in hospital settings are those cared for in neonatal and pediatric intensive care units, sometimes associated with mechanical devices.

Soft tissues and capillary beds can be compressed between a bony prominence and an external surface. Tissue ischemia occurs when compression slows blood flow to the skin and deeper tissues. The cells are deprived of oxygen and nutrients, and metabolic waste products accumulate, resulting in hypoxia and soft-tissue injury. If compression is not relieved, the injury progresses rapidly and a pressure ulcer forms.

Stages 1 and 2 are the most common stages of pressure ulcers in children (Figure 31–11). In stage 3, an ulcer forms as the subcutaneous tissue is exposed, causing a full-thickness injury. In stage 4, the ulcer deepens and extends to muscle, bone, or supporting tissues. See Table 31–7 for common sites and potential causes of pressure ulcers in children.

Clinical Tip

The site of greatest pressure in infants and young children is the occiput. Older children have increased pressure on the sacral and occipital areas.

Initial treatment for early stages of skin damage is removing pressure from the affected site until the skin has healed. Children who use leg braces for alignment and mobility are often put in

A

B

Figure 31–11 **The initial stages of pressure ulcer formation. *A*, Stage 1, an area of redness does not go away within 30 minutes of removing the pressure or skin irritant. Children with dark skin may have persistent red, blue, or purple discoloration. *B*, Stage 2, the skin looks rubbed or raw like a blister or abrasion, a partial-thickness injury with damage through epidermis, dermis, or both.**

TABLE 31–7 Sites and Potential Causes of Skin Breakdown

SITES	POTENTIAL CAUSES
Occipital region of scalp	Inability to lift head
Sacrum and buttocks	Confinement to bed or wheelchair
Legs and feet	Orthotics, leg braces, casts
Spine and neck	Scoliosis brace
Knees, elbows, heels of feet	Rubbing against bed sheet
Sternum, iliac crest	Prone positioning for mechanical ventilation

wheelchairs. Children who use wheelchairs may be put on bed rest with a pressure-reducing surface. Frequent repositioning is needed. A transparent film may be applied to affected red skin to minimize friction. Pressure ulcers are treated with dressings, such as hydrocolloids, gels or hydrogels, and calcium alginates that do not adhere to the wound.

Nursing Management

The Braden Q Scale (for children under age 5 years) or the Braden Scale are tools to assess the child's risk for pressure ulcers when hospitalized and when the child has a chronic condition with limited mobility. The nurse should assess the child for each of the following risk factors:

- Ability to change and control body position
- Amount of physical activity
- Ability to respond to the discomfort associated with pressure
- Degree to which the skin is exposed to moisture
- Movement of the skin against surfaces
- Food intake pattern
- Tissue perfusion and oxygenation

Carefully inspect the dependent skin surfaces of all infants and children confined to bed at least 3 times in each 24-hour period. Identify the size (length, width, and depth) and character of any skin lesion. Note any signs of infection, the appearance of wound edges, type of tissue at the wound base, and drainage. Describe any drainage amount, color, and type.

Develop protocols for pressure ulcer prevention so that children at high risk are identified and have appropriate interventions initiated (e.g., increased ambulation, frequent position changes, pressure-reducing surfaces, and moisture barriers). If the child is incontinent, change the diaper frequently to keep the skin clean and dry. Ensure an adequate intake of fluids, proteins, and vitamins to keep the skin healthy.

Moist wounds heal more rapidly than dry wounds because cell migration across the moist wound bed more effectively fights infection and removes cellular debris. Provide wound care and dressing changes according to agency guidelines. These guidelines may include saline irrigation, debridement, and a dressing appropriate for the wound condition. See Table 31–3 for types of wound dressings (see the *Clinical Skills Manual* SKILLS). Gauze wraps to hold the dressing in place help prevent skin damage caused by adhesives.

Teach parents of children with braces to inspect the skin under the braces every day for irritation (redness or blisters). Help the child use a mirror with a long handle to inspect skin on the bottom and sides of the feet, behind the knees, and on the lower legs. Check all edges of the braces for roughness or breakage that can pinch or scrape the skin. If any skin irritation is seen and redness does not go away within 30 minutes, do not put the brace back on until the skin heals. Inform the child's healthcare provider so that treatment can be started immediately. To reduce irritation, have the child wear cotton socks under the braces and make sure the shoes are large enough to accommodate the brace, socks, and the foot. Advise parents to return to a prosthetist regularly for brace refitting as the child grows.

Children who use a wheelchair are at risk for skin breakdown on the buttocks and lower back from the pressure of sitting for hours. A wheelchair cushion can distribute and shift the child's weight when sitting in the chair. Teach the child to change position frequently by doing wheelchair push-ups or by shifting the weight (leaning to the side or forward) for several minutes every 10 to 15 minutes. Make sure the child wears a safety belt when sitting in the wheelchair. Teach school personnel about the child's recommended protocol so they can provide opportunities in school to change positions and reinforce the routine.

Burns

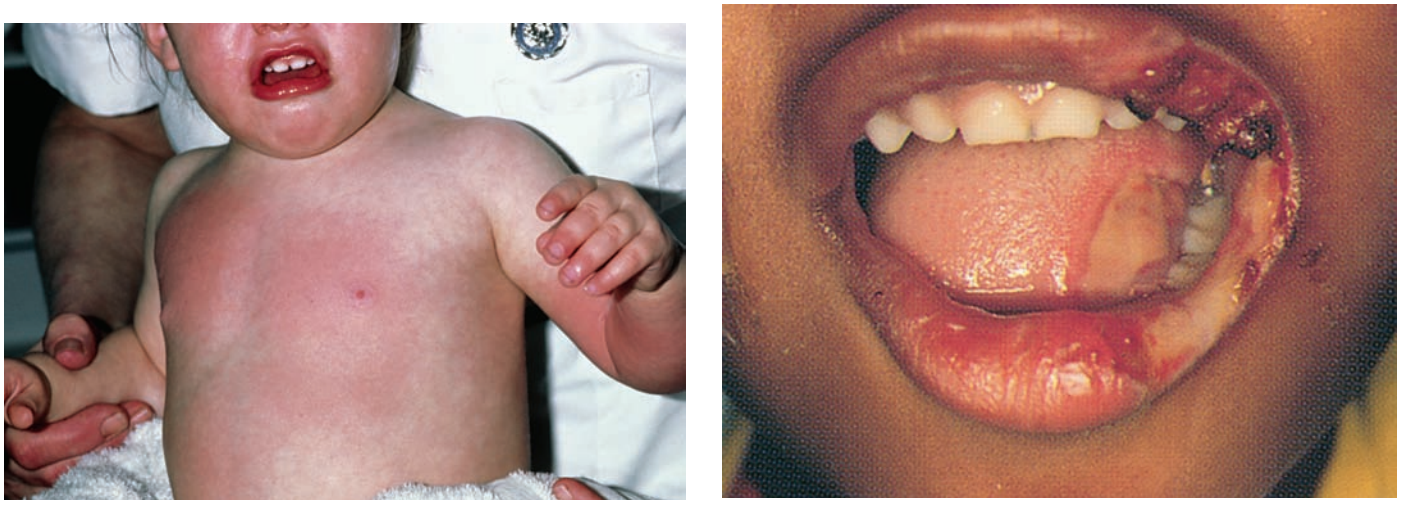
Burns are among the top five leading causes of injury and death in children between 1 and 14 years of age (National Center for Health Statistics, National Vital Statistics System, 2015). In the United States, 128,765 children and adolescents under age 19 years were treated for burns in 2013 (Centers for Disease Control and Prevention [CDC], 2015). Of these children, the majority were less than age 5 years (Vloemans, Hermans, van der Wal, et al., 2014).

The four main types of burns are thermal, chemical, electrical, and radioactive. Thermal burns, the most common in children, result from flames, scalds (such as coffee or grease), or contact with hot objects (such as a wood stove or curling iron). Chemical burns occur when children touch or ingest caustic agents. Electrical burns are caused by direct or alternating current in electrical wires, appliances, or high-voltage wires. Radiation burns result from exposure to radioactive substances or sunlight. Burns are also found in 10% of cases of child abuse (Hazinski, Mondozzi, & Baker, 2014). See Chapter 17 for more information about child abuse.

ETIOLOGY AND PATHOPHYSIOLOGY

Children at different developmental stages are at risk for different types of burns:

- Infants are most often injured by thermal burns (scalding liquids, house fires).
- Toddlers are at risk for thermal burns (pulling hot liquids or grease onto themselves), electrical burns (biting electrical cords), contact burns, and chemical burns (ingesting cleaning agents, button batteries, and other substances) associated with exploring the environment (Figure 31–12).
- Preschool-age children are most often injured by scalding or contact with hot appliances (curling irons, ovens).
- School-age children are at risk for thermal burns (playing with matches, fireworks), electrical burns (climbing high-voltage towers, climbing trees, and contact with electrical wires), and chemical burns (combustion experiments).
- Adolescents also experience thermal, chemical, and electrical burns, as well as radiation burns associated with sunbathing.



A B

Figure 31–12 *A,* Scald injury from hot liquid is a common thermal burn injury in infants and toddlers. Notice the distribution of the burned skin, a wide area on the upper chest where the hottest liquid fell, with a narrower area indicating the liquid cooled as it traveled down the chest. *B,* Electrical burn caused by biting on electrical cord. The burn is caused when the current arcs through the lips, often causing a full-thickness injury through the mucosa, muscle, nerves, and blood vessels. The labial artery may be injured and cause significant bleeding once the eschar falls off after 2 to 3 weeks.

SOURCE: ***A,*** Dr. P. Marazzi/Science Source. ***B,*** Courtesy of Dr. Lezley McIveen, Department of Dentistry, Children's National Medical Center, Washington, DC.

The depth of the burn depends on the temperature and duration of the heat application, and on the ability of tissues to dissipate the transferred energy. Immediately after the burn, the cell membranes are altered, leading to increased capillary permeability and extracellular fluid loss. Fluid and plasma shift into the interstitial spaces, causing edema and decreased circulating volume in the blood vessels. Capillary perfusion to most capillaries is decreased because of myocardial depression, leading to tissue ischemia. The child loses increased water, electrolytes, and heat through the injured epidermis. A hypermetabolic state develops from the stress response, and severe alterations in glucose, lipid, and amino-acid metabolism may last for months after the burn injury (Jeschke & Herndon, 2014). A high number of calories are needed in an effort to maintain body temperature and begin healing. Immunosuppression also occurs, which increases the risk for infection.

SAFETY ALERT!

Coffee, tea, soup, and other hot beverages are often served at temperatures high enough to cause a serious scald injury. To prevent scald injuries, adults should not hold infants in their laps while drinking hot beverages.

CLINICAL MANIFESTATIONS

Burns are classified by the depth of penetration into the skin layers. Partial-thickness burns, in which the injured tissue can regenerate and heal, may be either first or second degree. Full-thickness burns, in which the injured tissue cannot regenerate, are also known as third-degree burns. See *Pathophysiology Illustrated: Classification of Burns by Depth* for clinical manifestations by burn depth.

Signs of infection include purulent drainage, swelling, erythema, discoloration of wound margins, and pain in the uninjured skin around the wound.

CLINICAL THERAPY

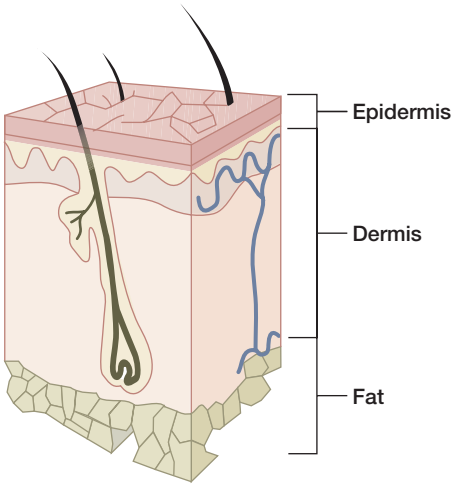
Assessment of Burn Severity. Burn severity is determined by the burn depth, percentage of body surface area (BSA) affected, and involvement of specific body parts. A Lund and Browder chart with BSA distributions for various body parts at different ages is used to calculate the total area affected by the burn injury (Figure 31–13). The palm of a child's hand (without fingers and thumb) is 1% of the child's BSA and can be used to make a quick estimate of the burn size. Reassessment of the extent of burn injury is performed 24 to 48 hours after the injury. The true extent of BSA burned and depth of burns may not be apparent for several days.

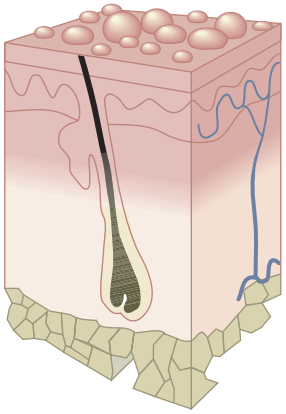
Criteria for pediatric burns that should be referred to a specialized burn center include (American College of Surgeons, Committee on Trauma, 2014, p. 101):

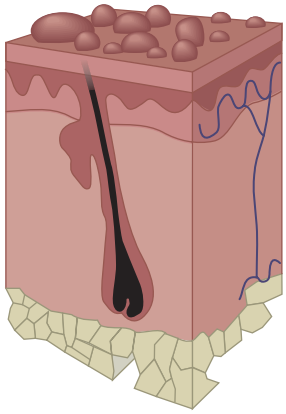
- Partial-thickness burn greater than 10% BSA and full-thickness burns of any size
- Burns involving the hands, face, eyes, ears, feet, genitalia, perineum, and skin over major joints
- Electrical burns, including lightning injury
- Chemical or inhalation injury
- Burns in a child with another medical condition or additional trauma that increases the risk for death or increased morbidity
- Need for special social and emotional or long-term rehabilitation support, including cases of suspected child maltreatment

Initial Treatment. The first step is to ensure that the child has an airway, is breathing, and has a pulse. Then stop the burning process by removing jewelry and clothing. Moist soaks or ice (if a small surface area is affected) is used to stop the burning process and to relieve pain. A tetanus vaccine booster is given if

Pathophysiology Illustrated: **Classification of Burns by Depth**

SUPERFICIAL PARTIAL THICKNESS (FIRST DEGREE)	PARTIAL THICKNESS (SECOND DEGREE)	FULL THICKNESS (THIRD DEGREE)
Damages only outer layer of skin; burn is painful and red; heals in a few days (e.g., sunburn)	Involves epidermis and upper layers of dermis; may have sparing of sweat glands and sebaceous glands; heals in 10–14 days	Involves all of epidermis and dermis; may also involve underlying tissue; nerve endings usually destroyed; requires skin grafting
Erythema, blanches on pressure, no bullae, peeling after a few days due to premature cell death	Blisters or bullae, erythema, blanches on pressure, pain and sensitivity to cold air, minimal scar formation	Skin may appear brown, black, deep cherry red, white to gray, waxy or translucent; usually no pain, injured area may appear sunken
		






more than 5 years have passed since the last vaccine, or when the child has not completed the full vaccine series.

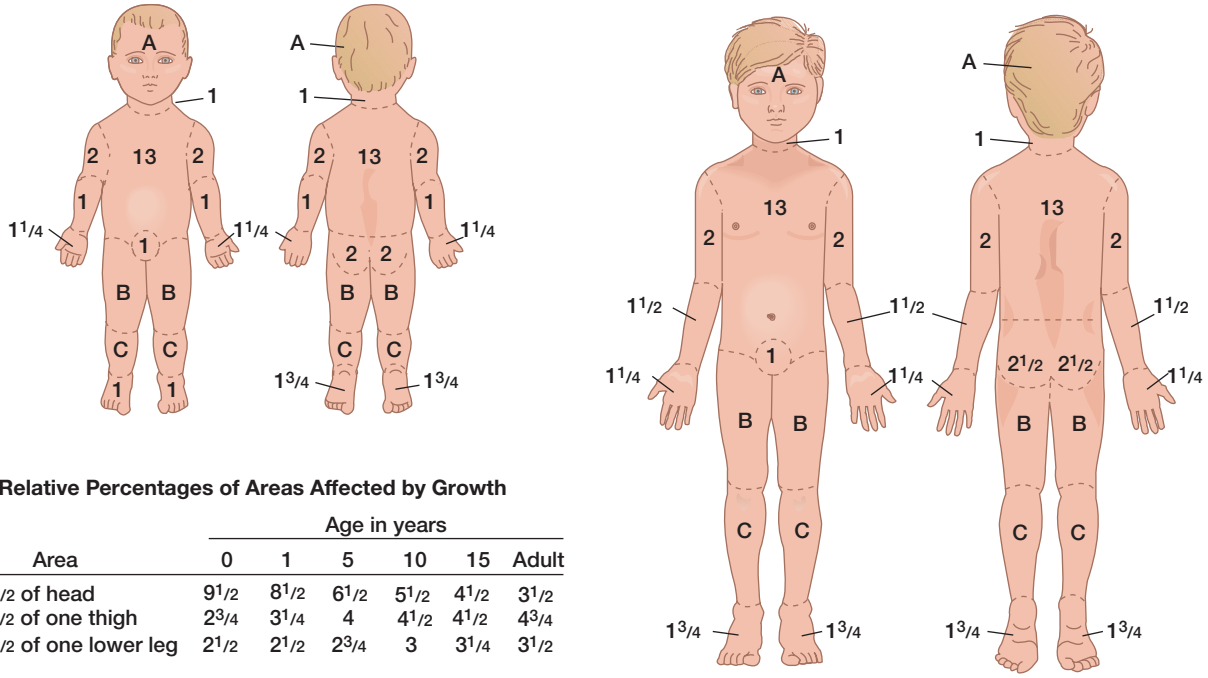
Treatment of Major Burns. The goals of treatment include decreasing burn fluid losses, preventing infection, controlling pain, promoting nutrition, and salvaging all viable tissue. Fluid resuscitation is necessary to maintain the cardiovascular and renal systems. Fluid shifts from the vasculature to the interstitial spaces (third spacing) soon after the burn and can cause hypovolemic shock. Fluid replacement for the first 24 hours after the injury is based on a fluid volume formula calculated from the child's body weight, affected BSA, and normal maintenance needs (e.g., the Parkland and Galveston formulas):

- *Parkland formula:* 4 mL × body weight (kg) × percentage of total BSA burned = total 24-hour fluid requirement in milliliters. Maintenance fluids must be added to the amount of fluid calculated with this formula.
- *Galveston or Shriners Burn Hospital formula:* 5000 mL/m^2 burned area + 2000 mL/m^2 of total BSA = total 24-hour fluid requirement in milliliters.

Lactated Ringer or normal saline solution is the preferred IV fluid. Half of the total volume calculated for the 24-hour period is infused over the first 8 hours, starting at the time of the burn rather than emergency department arrival time. The remainder is distributed evenly over the next 16 hours. Urine output is used to monitor end-organ perfusion. When the urine output reaches 1 mL/kg/hr in children weighing less than 30 kg or 50 mL/kg/hr in heavier children, the fluid rate is reduced (Hazinski et al., 2014). Efforts are also focused on maintaining the child's temperature because heat is lost rapidly through burned skin.

A temperature elevation to 38.0°C (100.4°F) is expected because of the high metabolic rate, not always a sign of infection. A lower temperature is of concern as a possible sign of sepsis or physiologic reserves are exhausted for temperature maintenance (Hazinski et al., 2014). Infection is a frequent complication and wounds are cultured to identify specific organisms and sensitivities before prescribing antibiotic therapy.

Aggressive pain management with intravenous opioids is needed around the clock and for all procedures. The burns cause



Relative Percentages of Areas Affected by Growth

	Age in years					
Area	0	1	5	10	15	Adult
A = 1/2 of head	9½	8½	6½	5½	4½	3½
B = 1/2 of one thigh	2¾	3¼	4	4½	4½	4¾
C = 1/2 of one lower leg	2½	2½	2¾	3	3¼	3½

Figure 31–13 Body surface area (BSA) percentages for estimating pediatric burn injuries by age group. The extent of burn injury is calculated by adding BSAs affected for each body region.

SOURCE: Data from Artz, C. P., & Moncrief, J. A. (1969). *The treatment of burns* (2nd ed.). Philadelphia: Saunders; Fenlon, S., & Nene, S. (2007). Burns in children. *Continuing Education in Anaesthesia, Critical Care & Pain*, 7(3), 76–80; Tschudy, M. M., & Arcara, K. M. (2012). *The Harriet Lane handbook* (19th ed., p. 99). Philadelphia, PA: Elsevier Saunders.

a significant emotional distress that increases the perception of pain. See Chapter 15 for pain management information. Cimetidine or other H_2 blockers may be ordered to prevent a burn stress ulcer. Medications to help manage the hypermetabolic state may include propranolol, oxandrolone, and insulin (D'Cruz, Martin, & Holland, 2013).

Special consideration is needed when burns involve certain areas of the body:

- Deep partial-thickness and full-thickness burns develop **eschar** (the tough leathery scab that forms over severely burned areas) with no elasticity. When the burn is **circumferential** (surrounds the chest or an extremity), blood flow can become restricted as a result of edema, leading to tissue hypoxia. An **escharotomy** (incision into the constricting tissue) may be necessary to restore peripheral circulation.
- Facial burns usually cause significant edema. Care must be taken to ensure airway patency. An ophthalmologist should assess burns to the eye and prescribe treatment. If the lips are burned, an infant may be unable to suck.
- Burns of the hands require careful management to maintain function. Special splinting and physical therapy are usually necessary.
- Perineal burns are at higher risk for infection because of frequent contamination with urine and stool. Frequent dressing changes are required. A urinary catheter is usually inserted but is removed once hydration status is stable to minimize the risk of urinary tract infection.

Wound Management. Burn wound care has several goals: (1) to remove necrotic tissue and speed wound debridement, (2) to maintain moist wound conditions and adequate circulation, (3) to conserve body heat and fluids, (4) to protect from infection, and (5) to control scarring and prevent scar contracture. Several treatment regimens are used to achieve these goals.

When the burn is extensive, the entire body is bathed to initiate debridement. Sedation, pain management, and anesthesiology support are used during debridement sessions. Intact blisters provide a natural, pain-free, sterile dressing. However, some healthcare providers break blisters open, believing that the fluid provides a medium for bacterial infection. The tissues should be carefully cut away when the wound is being prepared for skin grafting.

Various options are used for wound management after debridement. Traditional burn care for a partial-thickness injury involved the application of antibacterial agents, such as silver sulfadiazine (Silvadene) or mafenide acetate (Sulfamylon) after initial cleansing, followed by a dressing that was changed once or twice daily. However, silver sulfadiazine was found to be cytotoxic (Kim, Martin, & Holland, 2012).

Silver-based antimicrobial dressings (e.g., Aquacel, Acticoat) provide a sustained-release delivery of silver, valued for its antimicrobial property. These dressings also absorb exudate from the wound and can be left in place several days (Figure 31–14). When the dressing is removed, a layer of eschar may also be debrided. These dressing changes are often painful, so pain management is needed (see Chapter 15).

Hydrotherapy (whirlpool bath or shower) may be used to cleanse extensive wounds before debridement, to increase vasodilation and circulation, and to speed healing. The water loosens exudate, topical medications, and dead tissue, and it may help soak off dressings that adhere to the skin. Gentle washing is necessary to protect new epithelial cells. Superficial partial-thickness burns reepithelialize within 3 weeks.

Skin grafting is necessary with any deep partial-thickness or full-thickness burn. Often a biologic dressing (e.g., Integra or Biobrane) or **allograft** (cadaver skin from a skin bank) is used to cover deep burns until an **autograft** (healthy skin taken from a nonburned area of the child's body) can be performed. The biologic dressing or allograft is effective in decreasing infection risk and pain, protecting against fluid loss, and promoting

Figure 31–14 This child's scald burn is being treated with an Aquacel AG dressing, a silver-embedded dressing. Note the absorbed exudate that is visible through the burn dressing.

revascularization. An autograft is permanent. The autograft is placed after the wound is debrided in the operating room to reveal healthy, bleeding tissue. The donor site (where the autograft was harvested) is a new wound, causing pain and requiring close monitoring for signs of infection.

Vacuum-assisted wound closure (negative pressure wound therapy) is sometimes used for management of partial-thickness burns, graft sites, and other complex wounds. A pump generates a vacuum or suction to remove waste materials from the wound area. Once the burn site is debrided, a foam dressing is applied and sealed with adhesive before the device is attached. The vacuum over the surface of the wound draws out fluids, increases blood perfusion, decreases bacterial colonization, and draws wound edges together to speed healing. These devices are being used more often, but the U.S. Food and Drug Administration has not yet approved them for use in infants and children (U.S. FDA, 2014).

During the rehabilitation stage, pressure garments (e.g., Jobst) are used to reduce development of hypertrophic scarring and contractures. Such garments are worn 23 hours a day for 6 to 8 months to shorten the time of scar maturation and to reduce the thickness of the scars (Figure 31–15).

Severe morbidity is likely to occur with major burns. Significant scarring may occur despite the use of autografting and pressure garments. Contractures and loss of function are also possible. Children with major burns require comprehensive follow-up, sometimes involving repeated hospitalizations for surgery to release burn contractures or perform new grafting, or cosmetic surgery for scar revision.

Nursing Management

For the Child With a Burn Injury

Nursing Assessment and Diagnosis

Emergency assessment first focuses on the potential for life-threatening injuries that need immediate response. Assessment of the airway is necessary, especially when signs of smoke inhalation or burns to the face and neck are noted. Other potential injuries are important to identify when the mechanism of injury also includes a fall or explosion. Identify signs of respiratory distress and any potential bleeding source. A weak, thready pulse, tachycardia, and pallor are important signs of early shock that may provide clues to an internal injury.

Obtain information about the type of burn, when and how it happened, and first aid provided, along with a complete history. If a burn injury was preventable, parents may be emotionally stressed by feelings of guilt. Take care to avoid sounding accusatory when questioning parents about the injury. Be alert to signs of child abuse when the history does not match the injury (e.g., glove and stocking burns, popliteal or antecubital areas spared from burns where the child flexed the knees or elbows, contact burns from cigarettes or irons, and zebra burn lines from contact with a hot grate) (Figure 31–16). Photographs are often taken to document these injuries. Child neglect can be a factor in the burn of an inadequately supervised child.

Assess the extent of burn injury (BSA and depth). Frequently monitor the vital signs and pain control. Monitor the child's circulatory and respiratory status to identify signs of hypovolemia in the first 24 hours or fluid overload as capillary integrity is restored. A head-to-toe assessment is performed at the beginning of every shift, followed by system-specific assessments, depending on clinical findings and changes in the child's status. A urinary catheter may be inserted to enable close monitoring of urine output (see the *Clinical Skills Manual* SKILLS). Weigh the child daily, as the hypermetabolic state may result in weight loss if nutritional intake is inadequate. Be alert to signs of infection such as purulent drainage and edematous, red, or discolored wound margins.

Figure 31–16 **Burns of the hands or feet distributed like gloves or stockings are associated with child abuse. Contact burns on the soles of the feet in a pattern are also suspicious. Note the similar burn pattern on each foot.**

SOURCE: SPL/Science Source.

SAFETY ALERT!

If a burn is circumferential, completely surrounding an extremity, compartment syndrome often occurs. Assess for an increase in cyanosis, deep tissue pain, capillary refill time, and a decreased pulse distal to the burn. If these signs are detected, notify the healthcare provider immediately.

Assess the child's concerns over appearance and the stress of hospitalization. Determine if the child has memories or nightmares about the burn and arrange psychologic support as needed. Identify any family stressors that might need to be addressed during the child's care.

Common nursing diagnoses for the child with a major burn injury are included in the accompanying *Nursing Care Plan*. Additional nursing diagnoses for the child with a major burn might include the following (NANDA-I © 2014):

- ***Hyperthermia*** related to hypermetabolic state
- ***Body Image, Disturbed,*** related to burn injury
- ***Anxiety*** related to situational crisis and threat of death or disfigurement

Nursing Care Plan: The Child With a Major Burn Injury

1. Nursing Diagnosis: *Pain, Acute,* related to physical injury agents (NANDA-I © 2014)

GOAL: The child will verbalize adequate relief from pain and will be able to perform activities of daily living (ADLs).

INTERVENTION	RATIONALE
• Assess the level of pain frequently using pain scales (see Chapter 15).	• Provides objective pain measurement. Changes in pain location and intensity may indicate complications.
• Cover burns as much as possible.	• Temperature change or air movement causes pain.
• Change the child's position frequently. Perform range-of-motion (ROM) exercises.	• Reduces joint stiffness and prevents contractures and increases comfort.
• Provide diversional activities.	• Helps lessen focus on pain.
• Promote uninterrupted sleep with use of medications and comfort measures.	• Sleep deprivation can increase pain perception.
• Use analgesics and sedation (as appropriate) before all dressing changes and burn care. Use sedation when appropriate for major debridement.	• Helps to reduce pain and decreases anxiety for subsequent dressing changes.

EXPECTED OUTCOME: Child will verbalize adequate relief from pain and be able to perform ADLs.

2. Nursing Diagnosis: *Infection, Risk for,* related to trauma and destruction of skin barrier (NANDA-I © 2014)

GOAL: The child will have reduced risk for infection or have secondary infection identified early.

INTERVENTION	RATIONALE
• Take vital signs frequently.	• Increased temperature may be an early sign of infection, but it is also a common with the hypermetabolic state. A normal or decreased temperature may be a sign of sepsis.
• Use standard precautions (gown, gloves, mask) when wounds of a major burn are exposed. Do not allow anyone with an infectious disease to visit.	• Reduces risk of wound contamination.
• Clip hair around burns.	• Hair harbors bacteria and can irritate the wound.
• Keep burn dressing clean and intact.	• Helps reduce the number of bacteria introduced to the burned site.
• Do not place the IV in any burned area.	• Reduces risk of wound contamination.
• Administer oral or IV antibiotics for diagnosed infections as prescribed.	• Antibiotics help to clear the infection quickly.

EXPECTED OUTCOME: Child will have infection risk reduced, and secondary infections are diagnosed and treated promptly.

3. Nursing Diagnosis: *Fluid Volume: Imbalanced, Risk for,* related to loss of fluids through wounds and to subsequent excess fluid intake (NANDA-I © 2014)

GOAL: The child will maintain adequate urine output.

INTERVENTION	RATIONALE
• Monitor vital signs, capillary refill time, and pulses.	• The child is initially at risk for hypovolemic shock and needs fluid resuscitation (see Chapter 21).
• Administer IV and oral fluids as ordered.	• Careful calculation of fluid needs and ensuring proper intake helps keep the child properly hydrated.
• Monitor intake and output.	• The child is initially at risk for hypovolemia and then overhydration during fluid resuscitation.
• Weigh child daily using the same scale and amount of clothing.	• Significant weight loss or gain can help determine fluid imbalances.
• Insert urinary catheter if prescribed.	• Helps maintain accurate output measurement during critical care stage.
• Monitor for hyponatremia and hypercalcemia (see Chapter 18).	• Sodium is lost with burn fluid and potassium is lost from damaged cells, causing electrolyte imbalances.

EXPECTED OUTCOME: Child will achieve the expected urine output for age during each stage of acute burn treatment.

4. Nursing Diagnosis: *Mobility: Physical, Impaired,* related to joint stiffness due to burns (NANDA-I © 2014)

GOAL: The child will maintain maximum range of motion.

INTERVENTION	RATIONALE
• Arrange physical and occupational therapy twice daily for stretching and ROM exercises. Splint as ordered.	• Positioning in alignment and ROM exercises help to prevent contractures.
• Encourage activities to promote range of motion (toss a bean bag, mimic animal movements).	• Fun activities help the child with diversion and provide movement.

EXPECTED OUTCOME: Child will maintain maximum range of motion without contractures.

5. Nursing Diagnosis: *Nutrition, Imbalanced: Less than Body Requirements,* related to high metabolic needs (NANDA-I © 2014)

GOAL: The child will maintain weight and demonstrate adequate serum albumin and hydration.

INTERVENTION	RATIONALE
• Provide an opportunity to choose meals and snacks. Offer a variety of high-protein and high-calorie foods. Provide small frequent feedings.	• Encourages intake. General malaise and anorexia lead to poor healing.
• Encourage the child to have meals with other children.	• Socialization improves intake.
• Provide a multivitamin supplement.	• Vitamin C aids zinc absorption; zinc aids in healing.
• Provide enteral feedings as needed.	• A child with a burn greater than 10% of BSA cannot usually meet nutrition requirements without assistance.
• Weigh the child daily.	• Provides objective evaluation.

EXPECTED OUTCOME: Child will maintain weight, adequate hydration, and normal serum albumin.

Planning and Implementation

Care of the burned child involves various treatments designed to promote healing and prevent complications. These include analgesia and comfort measures, wound management, infection control, fluid and nutrition management, physical therapy, and psychologic support. See the *Nursing Care Plan* for several of these topics.

PROMOTE COMFORT

Assess the child's pain frequently and provide pain management around the clock with intravenous opioids (see Chapter 15). To reduce stress on the child, begin pain and sedation management as soon as possible for the initial debridement. Promote the child's comfort during periods of elevated temperature while keeping burns covered to reduce pain. Fluids

should be administered at the rate prescribed for resuscitation for the first 24 hours, and then adjusted as prescribed. Keep the room temperature at a comfortable level. Change bed linens as needed when the child perspires heavily.

PROVIDE WOUND CARE

The burned area is debrided and cleaned, often with a chemical enzyme in a whirlpool bath or shower. An antibacterial/antimicrobial dressing is applied. In some cases, a semipermeable wound membrane is applied to superficial partial-thickness burns. At each dressing change, the wound needs to be assessed for appearance, exudate, odor, appearance of surrounding tissue, and presence of granulation tissue.

Allografts or autografts may be put in place in the operating room after debridement to prepare the burned tissue for the graft. Following the grafting process, vacuum-assisted wound closure may be used over graft sites to maintain a moist environment for healing. Donor sites are treated as separate wounds. Splints may be required to promote healing when the skin over a joint is burned. The child may be kept on bed rest for several days following an autograft to protect the graft until it has a vascular supply.

PREVENT COMPLICATIONS

The healthcare team's goal is to prevent complications. Severe complications of burns include infections, pneumonia, and renal failure, as well as possible irreversible loss of function of the burned area. Significant scarring may occur regardless of autografting. Contractures and loss of function are also possible.

PROVIDE EMOTIONAL SUPPORT

Children with burns have received a profound insult to their body and their self-image. Fear and anxiety about disfigurement and scarring are common, especially among adolescents. The shock and pain of the injury cause increased stress, as do the unfamiliar surroundings and presence of healthcare providers.

Psychologic support is essential to the child's recovery. Continuity of healthcare providers is important in developing a trusting relationship with the child and family. Orient the child to their surroundings and give ample preparation for procedures, when possible. Encourage the child and parents to voice concerns, and show understanding and support for their concerns. Make appropriate referrals to social workers, chaplains, and child-life specialists to ensure that the child and family receive necessary services. See *Evidence-Based Practice: Psychologic Impact of Burn Injury.*

EVIDENCE-BASED PRACTICE | Psychologic Impact of Burn Injury

Clinical Question

How do the intensive treatments and long rehabilitation associated with a severe burn impact the child survivor and the family?

The Evidence

A qualitative review of 75 articles focused on the psychologic consequences of pediatric burns for the child and family. Findings revealed that injured children had anxiety, traumatic stress reactions, and behavior problems in the first months after the burn event, whereas parents had high rates of posttraumatic stress, depressive symptoms, and guilt feelings. After recovery, child survivors as a group had few differences (feelings of self-worth, body image, and social competence) from populations on which assessment tools were normalized. Some children had problems with social functioning and feeling stigmatized. A lower body image was noted more often in girls and those with more severe visible scarring. Family functioning was found to be comparable to norms, but parental stress was apparent. Reviewed studies linked the psychologic responses of parents and family functioning as important factors in the child's psychologic outcome (Bakker, Maertens, Van Son, et al., 2013).

A study was conducted to determine the prevalence of posttraumatic stress disorder (PTSD), depression, anxiety, and stress among parents (n = 120) and the child in the first 6 months after the burn injury. Signs of PTSD in the child were determined from an interview with the parent and the Child Behavior Checklist. Tools administered to parents included the Posttraumatic Diagnostic Scale, Depression Anxiety Stress Scale-21, and a scale to assess coping styles used in stressful situations. During the first month after burn injury, parents scored in the moderate to extremely severe range for depression, anxiety, and stress, but these scores lowered to normal or to mild range 6 months after the injury. During the first month, 25 (22%) parents had a probable PTSD diagnosis, but at 6 months, 28 (24%) parents had moderate to moderately severe posttraumatic stress syndrome (PTSS) or impaired functioning. Presence of PTSS in the child was a factor associated with PTSS in parents at 1 month and 6 months postinjury (De Young, Hendrikz, Kenardy, et al., 2014).

A study of 98 child survivors of a burn injury greater than 30% BSA before age 16 years and treated in a Shriners' burn center investigated the potential for development of personality disorders after the injury (mean = 13.9 years later). A structured clinical interview tool and the 16 Personality Factor Fifth Edition Questionnaire were used to identify personality disorders. Half of the survivors (n = 49, 51%) did not have a personality disorder. The most common personality disorders found were paranoid (19.4%), passive aggressive (18.4% and more common in women [27.5%]), and antisocial personality disorder (17.3% and more common in men [22.4%]). Development of a personality disorder was not associated with age at time of burn, burn severity, or facial or other visible burn scars. However, the overall prevalence of personality disorders was higher in these burn survivors than in the general population (Thomas et al., 2012).

Best Practice

Concern about the parents' psychologic response to the child's acute burn is important because higher levels of distress may impact the parents' ability to be emotionally available to help their child manage distress. Young children may also model their responses to the parents' behavior. All children with severe burns and their families need psychologic support to improve coping during the acute and rehabilitation phases of care and to achieve the best social and psychologic functioning. Such support involves nurses, child-life therapists, and mental health professionals.

Clinical Reasoning

When caring for a child with burns in a clinic setting, investigate the resources available for ongoing mental health support for the child and parents. Is attention being paid to the child's behavioral symptoms? What support is provided to parents? What additional resources could help children with acute burn care in the clinic setting?

Play therapy is encouraged for children, even if they can only observe initially. Play therapy serves several purposes for the child with a major burn:

- It provides an outlet for frustration, independence, and creativity.
- It promotes activities that challenge range of motion.
- It normalizes the child's daily routine.
- It encourages the child, who sees the progress other children make day by day.

Families are at risk for emotional stress. Forewarn them about the expected edema and the changes in the child's body. Parents often feel guilty and responsible for the child's injury. Help parents focus on recovery rather than past actions. Anxiety usually results from lack of knowledge about the severity of the burn and the child's status, especially in the early stages of burn care and admission to the hospital ICU or burn center. Include the family in the child's care whenever possible. Involve parents in their child's care so they learn how to change dressings, assess for infection and dehydration, and perform range-of-motion exercises to aid in the child's recovery.

DISCHARGE PLANNING AND HOME CARE TEACHING

Identify and address home care needs well in advance of discharge. Discharge planning may include instructing parents in nutrition and diet needs, safety in the home, protection of the burned area, wound care, signs of infection and actions to take, use of pressure garments, and range-of-motion exercises to prevent contractures. Provide support and encouragement to parents as they learn how to care for the child with a burn injury.

COMMUNITY-BASED NURSING CARE

Care of the child with a serious burn requires long-term therapy and rehabilitation. Long-term care commonly occurs in the home. Many burn centers use silver-embedded burn dressings to reduce the frequency of dressing changes needed. After discharge, visits to the burn clinic are needed 2 to 3 times a week for dressing changes. Sedation may be necessary, depending on the extent of injury and debridement needed. Parents may be instructed to give pain medication prior to arrival at the clinic to ensure that the child has good pain management.

Children with extensive burns or with burns in locations where scarring may limit function must often wear a pressure garment, and sometimes a face mask if the face was burned. The garment is removed only for bathing and laundering. The pressure garment may present a threat to the child's body image, but it is an important way to decrease scarring. Help families understand the need for the special garments and masks, and how to clean and care for them.

Clinical Tip

Moisturizing creams can be used after burns heal to relieve drying. The healed skin is highly sensitive to sunburn, so cover the area or use a sunscreen. The sunscreen will also help prevent hyperpigmentation after burn healing.

Continued physical therapy and occupational therapy are often needed to regain strength and dexterity for self-care skills and to prevent contractures. Emphasis is placed on returning to normal activities of daily living as soon as possible, such as returning to school. Some children have home tutors or computer connections to school for a time to ensure opportunities for learning while decreasing their risk of exposure to infection.

School reentry is often a traumatic experience, especially for older children and adolescents, because of the fear of rejection, decreased self-esteem, and impaired body image. In some cases, the child's primary nurse may visit the school of a child with a burn injury before the child returns to school—bringing photographs of the child, pressure garments, or other items—to inform classmates and allow them to explore their feelings about the child's burn injury. Some communities may offer support groups for families and children with burn injuries. Referral to these groups may be beneficial.

A major role of nurses in the community is prevention. Provide burn prevention information to parents at each health promotion visit. Become involved with a Safe Kids coalition or with local firefighters to help educate families and caregivers about ways to prevent scald burns and house fires. Examples of prevention messages include the following:

- Appropriate temperature settings for hot water heaters
- Keeping the handles of pots on the stove turned toward the wall and dishes with hot liquids out of the toddler's reach
- Keeping infants and toddlers off the lap when drinking hot beverages or eating soup
- Keeping matches, lighters, and flammable materials away from children
- Installing smoke detectors and replacing the batteries annually

MANAGEMENT OF MINOR BURNS

Many children with minor burns are cared for at home after an initial visit to the emergency department or urgent care clinic. Discuss home remedies for minor burn care. For superficial burns covering a small area, use moist soaks to stop the burning process and to relieve pain. Any open blisters are debrided, and a thin layer of antibiotic medication (e.g., Bacitracin, silver sulfadiazine) is applied over the burn. Do not place this medication close to the eyes or mouth. The burn is then covered with one or two layers of gauze. Acetaminophen with codeine may be prescribed for burn dressing changes at home. Burn dressings should be changed twice daily. The child should be seen within 48 hours of initial treatment to monitor progress. Alternatively, a burn dressing may be applied and changed every few days in the clinical setting so the wound can be monitored. See *Families Want to Know: Caring for Minor Burns*.

Evaluation

Examples of expected outcomes of nursing management are included in the *Nursing Care Plan*. Some additional outcomes include the following:

- The child expresses and shows signs of reduced anxiety.
- Effective pain management is provided for dressing changes.

Sunburn

Sunburn is a burn injury to the outer layer of skin caused by excess ultraviolet light exposure, or sun exposure after taking phototoxic drugs (acne medication, sulfonamides, tetracycline, nonsteroidal anti-inflammatory drugs, and birth control pills). Young children have less melanin to protect their skin against harmful ultraviolet (UV) rays. It is estimated more than 25% of a person's lifetime exposure to sunburns occurs before 18 years

Families Want to Know

Caring for Minor Burns

- Place burn under cool, running water to stop the burning process and to help reduce pain. Do not use ice, as it can cause more damage to the injured skin.
- Remove all clothing and jewelry from the burned area.
- Do not use butter or margarine on the burn as it may introduce bacteria into the wound.
- Topical application of gel from the leaf of an aloe vera plant may help promote healing (National Center for Complementary and Alternative Medicine [NCCAM], 2012).
- Apply a topical antibiotic such as bacitracin to the burned area and cover the area with a couple of layers of gauze. Keep the area clean and dry.
- Clean and change the dressing twice daily. The pain medication may be given about an hour before the dressing change is planned. The dressing may be saturated with sterile normal saline and gently removed if it adheres to the burn area. Reapply the antibiotic cream and cover.
- Monitor for signs of infection, such as odor, increased drainage, and increasing redness of the skin around the burn. Contact the healthcare provider if infection is suspected.

of age (Gupta & Cohen, 2012). A childhood sun exposure history that includes intense repeated sunburns and chronic overexposure to UV radiation for the purpose of tanning is strongly associated with the development of all three types of skin cancer (basal cell, squamous cell, and melanoma) in future years (Gupta & Cohen, 2012). Avoiding sunburn during childhood is believed to be more important than protecting skin during adulthood. Use of indoor tanning beds and facilities increases the risk for developing melanoma by 74% (Gupta & Cohen, 2012).

SAFETY ALERT!

Behaviors and skin characteristics that increase the risk for pediatric melanoma include light skin and eyes, freckling, skin with an inability to tan, family history of melanoma, immunosuppression, and ultraviolet radiation treatment for psoriasis (Gupta & Cohen, 2012). Other factors include intermittent intense sun exposure (e.g., blistering sunburns before 20 years of age) and frequent sun exposure without use of sunscreen.

Erythema, pain, skin tenderness, swelling, blistering, and itching usually develop between 3 and 5 hours after exposure to ultraviolet B (UVB) rays. Solar UVA rays penetrate more deeply into the skin. Increased vasodilation and vascular permeability result in the extravasation of fluid to the tissues (edema, vesicles, and bullae) and white blood cell migration to the damaged skin. The erythema peaks at 12 to 24 hours and subsides after 72 hours. Systemic complaints include malaise, poor sleep due to skin tenderness, fatigue, headaches, and chilling resulting from rapid heat loss.

Treatment is generally supportive. Pain can be relieved by cool compresses, local anesthetic sprays or creams, and an emollient to help keep skin from drying out. Nonsteroidal anti-inflammatory drugs (NSAIDs) may be used for pain relief and to reduce inflammation. See Chapter 15 for information on NSAIDs. Skin exposed by broken blisters is gently washed 2 to 3 times a day and covered with clean clothing or a sterile dressing if the sunburned skin is limited to a small area.

Professionalism in Practice Sun Tanning

The American Academy of Pediatrics policy statement on ultraviolet radiation (UVR) states that the deliberate exposure to artificial sources of UVR (e.g., tanning beds and facilities) and overexposure to the sun to increase vitamin D concentrations should be avoided (AAP, 2011). Nurses have an important role in educating adolescents about the risks for skin cancer and damage to the eyes from UVR exposure. Nurses can also work with community leaders to develop local policies that ban adolescents under age 18 years from using tanning facilities or tanning beds.

Nursing Management

Educate parents and children about preventing sunburn. Advise parents and children that repeated sunburns may lead to permanent skin damage, skin cancer, cataracts, and premature aging of the skin. See *Families Want to Know: Preventing Sunburn*.

Healthy People 2020

(C-20) Increase the proportion of persons who participate in behaviors that reduce their exposure to harmful ultraviolet (UV) irradiation and avoid sunburn

Hypothermia

Hypothermia is a condition in which the core body temperature falls below 35°C (95°F). This occurs when the heat produced by the body is less than the heat lost. Hypothermia is a life-threatening emergency that can occur in any season and any geographic location. Infants and young children are at risk because of immature temperature regulatory mechanisms, thinner skin, limited subcutaneous fat, and a high skin surface area-to-body mass ratio. Adolescents are at risk because of risk-taking behaviors such as drug and alcohol use and engaging in remote outdoor activities without proper equipment.

Primary hypothermia results from environmental exposure. As with newborns, heat is lost through radiation, conduction, convection, and evaporation. As the core body temperature falls, the body tries to conserve body heat and to rewarm the blood by vasoconstriction (to shunt blood to the body core). The body generates heat by increasing muscle tone and shivering. Hypothermia leads to increased blood viscosity, slower blood flow through the capillaries, and the potential for blood coagulation.

Families Want to Know

Preventing Sunburn

- Keep children out of direct sunlight as much as possible, especially between 10 a.m. and 4 p.m. Encourage children to play in the shade.
- Be aware that water, concrete, and sand reflect sunlight and increase exposure by reflecting UV rays up toward the skin.
- Minimize sun exposure by wearing a hat with a 3-inch brim, closely woven cotton long-sleeved clothing and pants, and wraparound UV blocking sunglasses with 99% UV blockage. Wear a T-shirt while swimming.
- Use sunscreen with a sun protection factor (SPF) of 30 or higher. Apply thickly to all exposed areas 30 minutes before sun exposure. Reapply 15 to 20 minutes after first sun exposure, and then again every 2 hours as needed. Reapply sooner if swimming, toweling off, or perspiring heavily.
- Use a waterproof sunscreen when swimming for protection in water that lasts 60 to 80 minutes. Then reapply. Avoid placing it near the eyes as it causes a chemical burn and pain. Call the poison control center immediately if eyes are exposed.
- Use UV blocking agents such as zinc oxide or titanium oxide for infants under 6 months of age because infants may absorb sunscreen chemical through their skin.
- If the child is taking any medications, check with the healthcare provider before exposure (some medications cause hypersensitivity to sunlight).
- Adolescents should avoid indoor tanning facilities and artificial tanning devices because the rays are as damaging to the skin as the sun.

Symptoms of mild hypothermia (32 to 35°C [89.6 to 95.0°F]) include slurred speech, poor coordination, poor judgment and inappropriate behavior, shivering, and muscle stiffness. Symptoms of moderate hypothermia (28 to 32°C [82.4 to 89.6°F]) include depressed respirations, slow pulse, low blood pressure, pale or cyanotic color, shivering, and dilated pupils. Lethargy, mental impairment, irrational thinking, hallucinations, and coma develop as the central nervous system becomes depressed. Profound hypothermia (body temperature below 28°C [82.4°F]) is characterized by apnea, no shivering, low blood pressure, ventricular fibrillation, dilated and unresponsive pupils, and coma.

Clinical therapy focuses on resuscitation, if necessary, and gradual core body rewarming. The child who has profound hypothermia should receive cardiopulmonary resuscitation until the body temperature returns to normal because the hypothermia may have preserved vital organs. Aggressive techniques for rewarming may include humidified, warm oxygen; warmed intravenous fluids; warm packs to the core circulation areas (axillae, groin, and neck); and peritoneal lavage and dialysis. Hypoglycemia is a common complication and is treated with IV glucose.

For mild hypothermia (temperature above 35°C [95°F]), external heat lamps, immersion in warm water, and an electric blanket are used.

Nursing Management

Monitor vital signs and urine output during rewarming. Educate parents to layer children's clothing in cold climates, recognize signs of hypothermia, decrease time of exposure to cold, and know how to treat mild hypothermia. Teach school-age children and adolescents who go on camping and hunting trips how to recognize and manage hypothermia in themselves and others. Teach preventive techniques such as avoiding riding snowmobiles or walking on ice that is not known to be deep enough to support the weight.

First aid for hypothermia includes moving the child to a dry area and removing any wet clothing. Replace with warm, dry clothing, and encourage the child to drink a warm, high-calorie liquid, if possible. If a child becomes hypothermic during a camping trip or other outing, a warm person should get into a sleeping bag (or under the blankets) next to the child after any wet or heavy clothing is removed. This action will trap heat the child's body generates and provide passive rewarming by the other person.

Frostbite

Frostbite is a cold injury in which the skin tissue is exposed to temperatures below freezing for more than an hour when environmental protection is inadequate. Areas of the body at high risk for frostbite include the hands, feet, cheeks, nose, and ears. Ice crystallizes in the tissues, resulting in dehydration of the cells and ischemic damage. Frostbite can also occur if a chemical cold pack used for first aid is left in contact with the skin for an extended period.

Clinical manifestations vary by the severity of injury. In mild or superficial frostbite, the skin appears reddened or mottled, edematous, and stiff, and transient tingling or burning is present. In severe or deeper frostbite, the skin is gray or mottled, edematous, hard with no rebounding, and numb.

With superficial injury, rapid rewarming causes a flush and the sensation of tingling, burning, or prickling in the affected area. With deeper injury, the skin may appear mottled and cyanotic followed by erythema, swelling, and burning pain with rewarming. Vesicles and bullae develop in 24 to 48 hours, which slowly heal. The extent of injury is not initially apparent.

If frostbite is suspected, get the child to a warmer environment and remove any wet clothes. Because the frostbitten area may be numb, protect it from trauma. Slowly rewarm the area to decrease the chance of cellular damage by immersing the affected part in warm water between 40°C and 42°C (104.0°F and 107.6°F) until thawed. Analgesics are given to treat pain caused by thawing. Gently clean the affected skin with saline and cover it with sterile dressings. Wound care may be similar to that provided to a child with burns. Physical therapy may be important to improve circulation and maintain function.

Nursing Management

As with hypothermia, the goal of management is prevention. Teach parents to layer children's clothing for warmth and to pack extra blankets and clothing if cold temperatures are expected

during outdoor activities. Teach adolescents how to avoid frostbite during hunting and other cold weather expeditions. Wet clothing and gloves should be changed quickly.

Early care is instrumental in minimizing permanent injury. Severe frostbite requires hospitalization, fluid management, dressing changes, and careful attention to diet. Provide emotional support to the child and family while they wait to learn the full extent of injury and disability.

Bites

ANIMAL BITES

Dog bites accounted for nearly 134,000 emergency department visits in 2013 for children and youth less than age 20 years (National Center for Injury Prevention and Control, 2015). Children, and especially boys, ages 5 to 9 years have the highest rate of dog bites (CDC, 2014). In many cases, the child knows the dog or cat, and most bites occur in the home or a familiar place. Bites are often associated with the child's inappropriate behavior, such as teasing, rough play, or interfering with feeding or care of puppies. Other animals that may bite include cats, birds, turtles, and wild animals such as bats, squirrels, and raccoons.

Assessment includes noting the location and number of puncture wounds, abrasions, lacerations, and crushing injuries; redness or swelling at entry sites; redness extending out from site (possible cellulitis); and any drainage related to the bite. Damage to nerves, muscles, tendons, and vascular structures is identified. Dog bites tend to be crushing rather than clean, sharp lacerations. Cat bites tend to be puncture wounds; 50% become infected (AAP, 2015, p. 205). Head and neck bites require radiographic examination to rule out any associated injury, such as trauma to the airway or a depressed skull fracture.

Initial treatment involves irrigation of the wound, removal of devitalized tissue, and application of a clean dressing. Povidone-iodine solution (a virucidal agent) may be used in some cases to irrigate the wound. Sedation and pain management may be needed for some children. Puncture wounds may be debrided in the operating room. Prophylactic antibiotics may be prescribed to reduce the risk for infections. A delay in seeking care after the bite is associated with a greater risk for infection.

Wounds may be closed with adhesive strips rather than suturing because of the potential for infection. Severe bites sometimes require surgical closure or reconstruction. Wounds over joints should be immobilized and elevated. The major complication of bites is infection (such as cellulitis, septic arthritis, or osteomyelitis), which may require hospitalization.

Dog bites should be reported to animal control, and the dog should be confined and observed for 10 days for signs of rabies. Cat bites are also dangerous because cats are less commonly immunized against rabies. If the animal develops rabies during that interval, human rabies immune globulin (HRIG) and rabies vaccine is administered immediately, followed by a rabies vaccine injection on days 3, 7, and 14 following the first injection. HRIG and rabies vaccine are given immediately to all children bitten by wild animals in which rabies cannot be excluded. See Chapter 16 for a description of rabies treatment.

Nursing Management

If a child is bitten by an animal, obtain information about the extent of the injury, circumstances surrounding the attack, present location of the animal, and attempts to assess the animal's health.

To decrease infection, the wound is gently washed with antibacterial soap and water followed by high-pressure irrigation (unless it is a puncture wound) with large quantities of sterile saline or lactated Ringer solution. An 18-gauge needle on a 60-mL syringe may be used to provide high-pressure irrigation. A clean dressing is applied and the affected body part is elevated to reduce bleeding. Check the child's immunization record to determine whether a tetanus booster is necessary. Teach parents how to care for the wound and signs of infection that indicate a need to return for care.

Prevention of animal bites is another important nursing role (see *Families Want to Know: Preventing Animal Bites*).

HUMAN BITES

Human bites are more common than most people realize. Toddlers, young children, and adolescents often receive human bites during altercations. The skin may be broken, with erythema, abrasion, bruising, or laceration. Because the mouth harbors many bacteria, infection is fairly common. Assess the risk for hepatitis B and HIV infection. Initial treatment includes irrigating with sterile saline and debridement. Antibiotics may be prescribed to prevent systemic complications. Parents should be instructed about how to care for the wound and to observe for infection.

Families Want to Know

Preventing Animal Bites

General Guidelines for Pets in the Home

- Never leave a young child alone with an animal.
- Do not buy or adopt a pet unless you are confident of your child's ability to respect it.
- Spay or neuter the pet to reduce aggression.

Teach Children the Following Rules

- Avoid all unfamiliar animals and report them to a parent.
- Avoid contact with all wild animals. If an animal (wild or unknown) is sick or acting strangely, notify the health department.
- Do not touch an animal when it is eating, sleeping, or nursing.
- Never overexcite an animal, even in play. Do not roughhouse or play games that stimulate aggressive behavior. Do not tease or throw objects at an animal.
- Never put your face close to an animal. Seek permission before hugging or petting an animal.
- If approached by a dog, stay calm, stand still, talk softly, and back away slowly until the dog loses interest; do not run.
- If attacked, pretend to be a tree or a log and protect the face. If knocked down, curl into a ball and protect the face and neck.

INSECT BITES AND STINGS

Insect bites and stings occur frequently in children and usually are not a cause for concern. Exceptions include bites or stings by insects that carry parasites or communicable diseases (ticks, mosquitos), those of a venomous nature (spiders), and those that produce an allergic reaction. A small percentage of the population is sensitized to *Hymenoptera* (bee, wasps, fire ants) stings and has a generalized response. See Table 31–8 for clinical manifestations of insect bites and stings. For a discussion of communicable diseases carried by ticks and mosquitoes (e.g., Lyme disease, Rocky Mountain spotted fever, West Nile virus, malaria), see Chapter 16.

Nursing Management

The goal of nursing care is prevention. Become familiar with the harmful insects in your area, so you can identify them and recognize their effects. Teach children to avoid spiders and other biting or stinging insects. Also, teach children to stay calm when a bee or wasp approaches and to slowly walk away without swatting. Many commercial repellents (OFF, Cutter's, Deep Woods OFF) are available. Most products contain DEET (diethyltoluamide) or oil of lemon eucalyptus. They are effective against many insects, including mosquitoes, fleas, ticks, and chiggers, but do not repel stinging insects.

Warn parents against using heavily perfumed shampoos, powders, soaps, or lotions. Do not dress children in bright-colored or floral print clothing when outdoors, as these may attract insects. Avoid eating sweet foods and beverages outdoors as these will attract bees and wasps. Bees and wasps may crawl into a canned beverage and not be seen. Pour beverages into a cup rather than drinking from a can to prevent stings to the mouth and lips.

Household pets may be a source of fleas or ticks. Encourage frequent inspection of pets and preventive treatments against fleas and ticks before pets are allowed prolonged contact with children.

When a systemic reaction to *Hymenoptera* has occurred, the child should wear a medical alert identification and carry an emergency kit with epinephrine (see Chapter 22). Teach parents and school personnel how to administer epinephrine. Desensitization injections may be given.

SNAKE BITES

Venomous snakes are found in most areas of the country. During warm months, snakes are active and likely to bite if disturbed. Fortunately, many bites are dry, delivering no venom. Fatalities are rare.

Rattlesnake, copperhead, and cottonmouth venom is composed of enzymes and toxins that cause hemolysis and tissue necrosis. Coral snake venom causes neuromuscular paralysis that can affect breathing and lead to respiratory arrest (Wilbeck, & Gresham, 2013). The amount and toxicity of the venom injected has an impact on the consequences of the snakebite. Because children usually receive a higher amount of venom relative to body mass, their response may be greater than that of an adult.

Puncture marks, white wheal, and burning sensation appear at the site of the bite. With envenomation erythema, bruising and edema rapidly develop and extend from the site for up to 24 hours. Systemic signs include dizziness, tachycardia, nausea, vomiting, diarrhea, sweating, chills, and muscle twitching. Signs of a severe response may include hypotension, altered consciousness, bleeding from multiple sites (disseminated intravascular coagulation), pulmonary edema, and renal failure. Coral snake neurologic signs may include diplopia and ptosis, difficulty speaking and swallowing, hypersalivation, and altered mental status (lethargy, drowsiness, or euphoria).

Clinical therapy involves immobilization of the extremity and a cold compress to slow the spread of the venom. Laboratory studies include complete blood count, platelet count, coagulation studies, electrolytes, and renal function. Attempts to identify the snake causing the bite should be made to determine if it is venomous. A cell phone photograph of the snake is useful in identifying whether the snake is venomous. The poison control center is contacted to obtain treatment guidelines. Specific antivenom (often made with horse serum) is usually administered within 4 to 6 hours. CroFab, a newer antivenom used for cottonmouth, copperhead, and rattlesnake bites, has a lower rate of hypersensitivity reactions. Children at risk for severe hypersensitivity reaction are pretreated with antihistamines and corticosteroids. Monitor children treated with CroFab for thrombocytopenia, bleeding, or development of coagulopathy due to hemolytic effect of venom. Acetaminophen and codeine may be prescribed for pain management. A tetanus booster is given if vaccination status is unknown or the tetanus series is incomplete.

Nursing Management

Nursing care involves assessing the child for initial and progressive signs of envenomation. Try to keep the child calm to slow the circulation. First aid involves immobilizing the extremity, keeping it in a dependent position to slow the spread of venom, and cold compresses. Hands with a bite should be elevated after splinting in functional position. Ice should not be used. Rings or constricting items should be quickly removed from the injured extremity. Monitor the distal extremity's color, pulse, and sensation, and measure the circumference of the extremity above and below the affected extremity; reassess every 15 to 30 minutes to track progression of edema and response to treatment. Clean the wound with germicidal soap and water.

The child receiving antivenom may be cared for in the critical care unit. The antivenom is diluted in saline and slowly administered intravenously as ordered. Administer the antihistamines after tests for sensitivity to horse serum are completed. Have resuscitation equipment on hand in preparation for an anaphylactic reaction. Help locate additional antivenom if the hospital does not have an adequate supply. At time of discharge, educate parents of children who receive antivenom to monitor for unusual bleeding and to contact the health professional if noted. NSAIDs should not be used for 2 weeks after discharge because of increased bleeding risk.

Provide emotional support to the child and family. Teach children and their families to avoid future snakebites.

Contusions

Contusions are soft-tissue injuries that have a variety of causes. Often it is difficult to assess whether an injury has caused underlying tissue damage. An injury does not have to break the skin to result in internal damage. Radiographic examination may be necessary to rule out broken bones or further tissue damage. Signs and symptoms that indicate a need for treatment include swelling that does not subside within 72 hours, intense pain, inability to move the injured part, and infection. Elevate the injured extremity and apply ice as soon as possible after injury. This can reduce inflammation and swelling in the area.

Foreign Bodies

Many skin injuries result from penetration of foreign particles. Common substances include gravel from abrasions, bee stingers,

TABLE 31–8 Clinical Manifestations of Insect Bites and Stings

TYPE OF BITE AND CLINICAL MANIFESTATIONS	CLINICAL THERAPY
MOSQUITOES AND FLEAS	
Local inflammation results from injected foreign protein or chemicals. • Local reaction: discrete, red papules and edema at the bite site with itching, burning, pain, and hives; minimal discomfort; pruritic wheals and bullae tend to develop with repeat exposure. • Systemic reaction: wheezing, urticaria; laryngeal edema; shock.	Local reactions: • Apply cold compresses or ice to the site. • Antihistamine medication. Systemic reactions need emergency medical treatment.
BED BUGS	
Local inflammation results from injected saliva, an anesthetic and anticoagulant. • Local reaction: numerous pruritic papules, often in pattern of three papules; child often wakes up with numerous lesions on exposed skin areas that were not present the night before. • Systemic reaction: rare severe allergic reaction.	Local reactions: • Keep skin clean. • Topical corticosteroids may be applied. • Antihistamines may be prescribed. • Oral corticosteroids may be prescribed for severe allergic reaction. • Treat infested areas, and discard infested bedding.
BEE OR WASP STING	
Venoms contain enzymes that affect vascular tone and permeability. • Local reaction: mild, local pain; erythema and edema. • Systemic reaction: generalized urticaria, flushing, angioedema, pruritus; wheezing; dizziness, hypotension; abdominal pain, vomiting, diarrhea; anaphylaxis is rare.	Local reactions: • Remove stinger as soon as possible. • Apply cold compresses and elevate extremity. • A dash of meat tenderizer (papain powder) and a drop of water massaged into the skin for 5 minutes relieve the pain. • Antihistamine medication. Systemic reactions are treated with glucocorticoids and antihistamines or epinephrine. Desensitization for severe reactions.
FIRE ANTS	
Venom is hemolytic and neurotoxic, causing a histamine-like response. • Local reaction: a black center at the point of the bite, or trail of lesions across skin; initial wheal becomes a vesicle in a few hours; in 24 hr the fluid is cloudy, and the vesicle has a red halo; pruritus, erythema, edema, induration. • Systemic and anaphylactic reactions can occur.	Local reactions: • Ice or cold compresses. • Antihistamine medication. • Elevate extremity. Systemic reactions—same as bees and wasps.
BLACK WIDOW SPIDER	
Venom is neurotoxic. • Local reaction: stinging sensation at time of bite; localized edema and erythema, two fang marks, petechiae branching from site. • Systemic reaction in 1–3 hr, symptoms peak in 3–12 hr, diminish in 72 hr; muscle rigidity of torso and abdomen, priapism, muscle cramps near the bite; malaise, sweating, nausea, vomiting, dizziness, restlessness, insomnia, and diaphoresis; hypertension and arrhythmias; oliguria.	Ice Diazepam and opioids for pain management. Antihistamine medication. Hydrocortisone may decrease the inflammatory response. Antivenom IV is used in severe reactions after negative skin test for hypersensitivity to horse serum.
BROWN RECLUSE SPIDER	
Venom contains proteolytic enzymes and sphingomyelinase D, a cytotoxic factor. • Local reaction: within 2 hr, sinking blue macule with a halo of inflammation at the bite site; pain; a hemorrhagic blister forms in 1–2 days with a necrotic ulcer seen when it breaks. Most ulcers are 1–2 cm (0.4 to 0.8 in.) in meter, but some progress to 15 cm (6 in.) in meter with full-thickness injury. • Systemic reaction: fever, chills, nausea and vomiting, and hemolysis.	Ice Cleanse the wound and good wound care. Elevate extremity. Analgesics. Oral anti-inflammatory agent. Antibiotics for secondary infection. Excision and skin grafting in cases of severe necrosis.

Bedbugs: What nurses need to know. *American Journal of Nursing, 113*(10), 58–62; Camp, N. E. (2014). Black widow spider envenomation. *Journal of Emergency Nursing, 40*(2), 193–194.

and splinters. Treatment of superficial foreign bodies involves irrigating the wound to try to forcibly dislodge the debris. A deeply embedded foreign body is best removed under medical supervision to avoid permanent injury or scarring.

Lacerations

Lacerations are cuts or tears to the skin. In many cases, the cut is minor and can be managed at home with gentle cleansing, antibiotic ointment, and a bandage. More extensive lacerations and those on the face or over joints often need suturing to promote healing and reduce scarring. Laceration repair is performed after wound cleansing and appropriate local analgesia to control pain. Sutures or dermal adhesive may be used. Sutures are usually removed about 7 days later.

Chapter Highlights

- Wound healing has three overlapping phases: hemostasis and inflammation, tissue formation, and maturation.
- Contact dermatitis is a skin inflammation that occurs following direct contact with an allergen that causes an immune response, or with an irritant that causes no immune response.
- Superabsorbent disposable diapers reduce the frequency and severity of diaper dermatitis because, when wet, a gel forms inside the diaper keeping moisture away from the skin.
- Seborrheic dermatitis is an inflammatory skin condition due to an overgrowth of *Malassezia furfur* yeast in areas of sebaceous gland activity. Lesions are commonly found on the scalp, nasolabial folds, behind the ears, and intertriginous areas.
- The classic impetigo lesion begins as a vesicle surrounded by edema and redness. The vesicle fluid turns cloudy and ruptures, leaving a honey-colored crust on an ulcerated base.
- Athletes are at high risk for community-acquired methicillin-resistant *Staphylococcus aureus* because of their potential for frequent skin-to-skin contact, cuts or abrasions, wound contact, and shared items.
- Folliculitis, a superficial inflammation of the pilosebaceous follicle, may be associated with *Pseudomonas* exposure in a poorly chlorinated pool or hot tub.
- Children with cellulitis appear ill with fever, chills, malaise, and enlarged lymph nodes. The infected site is red or lilac in color, warm, edematous, and tender with an indistinct border.
- Viral skin infections include molluscum contagiosum and warts (papillomavirus).
- Oral thrush (candidiasis), a fungal infection, is characterized by white patches that resemble coagulated milk on the oral mucosa and may bleed when removed.
- Children being treated for tinea capitus may develop an "id" hypersensitivity reaction rash to the fungal antigen, and this is not an allergic reaction to the medication.
- Drug reactions vary in severity from a simple allergic reaction and erythema multiforme minor to potential life-threatening conditions, such as Stevens–Johnson syndrome and toxic epidermal necrolysis.
- Treatment of atopic eczema involves hydration and lubrication of the skin by bathing followed by emollients to trap in skin moisture. Topical corticosteroids are used to treat skin flares and then discontinued.
- Acne medications, tretinoin or isotretinoin, are phototoxic, resulting in sunburn with even minimal exposure. Protection with sunscreen or protective clothing is important to prevent significant sunburn.
- Psoriasis is chronic skin condition with pruritic, thick, silvery, scaly erythematous plaques that have irregular borders surrounded by normal skin.
- Epidermolysis bullosa is a rare, autosomal dominant, severe chronic blistering skin disorder that occurs with minor trauma.
- Treatment for lice includes a pediculicide applied to the hair and combing the hair with a fine-toothed comb to remove all the nits. Depending on product used, a second treatment may be needed in 7 days.
- Scabies is a mite infestation in which the female mite burrows under the skin to lay eggs, which causes irritation and intense itching.
- Hemangiomas undergo a period of rapid growth during infancy before involuting. The rapid growth may cause significant complications, such as pressure on the airway, eye, or ear canal.
- Children at greatest risk for pressure ulcers are those with limited mobility, sensory deficits, or the inability to change positions. Tissue ischemia occurs when the soft tissues and capillary beds are compressed between a bony prominence and another surface.
- Of the four main types of burns (thermal, chemical, electrical, and radioactive), thermal burns are most common in children. Infants, toddlers, and preschool-age children most commonly suffer scald burns. Other types of thermal burns include flames and contact with a hot object.
- Initial treatment for a child with a significant burn injury includes emergency assessment of the airway, breathing, and circulation and stopping the burning process by removing jewelry and clothing, and applying moist soaks or ice.
- More than 25% of a person's lifetime exposure to the sun occurs by 18 years of age. Repeated blistering sunburns during childhood increase the risk for development of melanoma.
- Children are at greater risk for hypothermia because of their thinner skin, limited subcutaneous fat, and high surface area to body mass ratio. Body heat is lost more quickly in water or when clothing is wet.

- Frostbite occurs when ice crystallizes in the tissues, causing cellular dehydration and ischemic damage.
- Children at highest risk for dog bites are those 5 to 9 years old. Most children know the dog that bites them.
- Insects and spiders with venomous bites include bees, fire ants, black widow spiders, and brown recluse spiders.
- Venomous snakes living in the wild in the United States include rattlesnakes, copperheads, water moccasins, and coral snakes. Initial treatment includes calming the child, immobilization of the extremity, and applying cold compresses to slow the spreasd of the venom.

Clinical Reasoning in Action

Twelve-year-old Rebecca is admitted to the burn unit with a scald burn from spilling a pot of boiling spaghetti water on her chest, abdomen, and legs. The burn is classified as a partial-thickness burn covering 12% of her body surface area (BSA) and full-thickness burn covering 3% of BSA. IV fluids are started in the emergency department and a continuous infusion of morphine is given for pain. Her temperature is 101.0°F (38.3°C). The initial debridement of the burns is performed in the operating room so that Rebecca is anesthetized and does not feel pain from the procedure. A silver-embedded dressing is applied to her partial-thickness burns, and a biologic dressing is placed over the full-thickness injury. Following debridement, Rebecca is put on a high-calorie, high-protein diet to help meet her increased nutritional requirements. Her parents are encouraged to bring in foods Rebecca enjoys to encourage her to eat. Wound care around the biologic dressing is performed twice a day, and all burn sites are inspected for signs of infection. The dressing over the partial-thickness burns is replaced every 3 days. Pain medication for wound care is provided through the IV. After several days, Rebecca is scheduled for an autograft for the full-thickness injury. Rebecca's nutritional intake and urine output are carefully monitored while she is hospitalized. Physical therapy is initiated to maintain range of motion and to prevent contractures.

The nurse talks with Rebecca and her family about what to expect as the burns heal. Education of the family includes signs and symptoms of infection and the care of the graft donor site and the graft site. After a few days in the hospital, Rebecca is discharged with daily follow-up in the burn clinic for wound care.

1. Which IV fluid is most likely used to treat Rebecca when she is admitted to the emergency department? Why?
2. Why is it important to monitor Rebecca's urine output?
3. What are the advantages of the type of dressing used for Rebecca's partial-thickness burns?
4. What regular assessments of Rebecca's burn sites should be performed?
5. What are some high-protein, high-calorie foods that might appeal to Rebecca?

Appendix B
Blood Pressure Tables

TABLE B–1 Blood Pressure Levels for Boys by Age and Height Percentile

Use the child's height percentile for the age and gender from the standard growth charts found in Appendix A. A blood pressure value at the 50th percentile for the child's age, gender, and height percentile is considered the midpoint of the normal range. A reading at or above the 95th percentile indicates hypertension.

		SYSTOLIC BP (mmHg)							DIASTOLIC BP (mmHg)						
		PERCENTILE OF HEIGHT							PERCENTILE OF HEIGHT						
Age (Year)	BP Percentile	5th	10th	25th	50th	75th	90th	95th	5th	10th	25th	50th	75th	90th	95th

Appendix D
Selected Pediatric Laboratory Values

All laboratory value intervals listed are approximate. Consult your local laboratory for guidelines as to normal values for the specific testing procedures used.

Normal Blood Chemistry and Hematology Value Intervals

Albumin (S)[1]

1 month–1 year:	2.8–4.8 g/dL
1–18 years:	3.2–4.7 g/dL

Alkaline Phosphatase (S)[1]

Age	Male Units/L	Female Units/L
1–30 days	75–316	48–406
1–3 years	104–345	108–317
4–6 years	93–309	96–297
7–9 years	86–315	69–325
10–12 years	42–362	51–332
13–15 years	74–390	50–162
16–18 years	52–171	47–119

α-Fetoprotein (AFP) (S)[1]

Newborn:	50–100,000 ng/mL
1–3 months:	40–1000 ng/mL
4 months–18 years:	0–12 ng/mL

Bilirubin (S)[1]

Conjugated:	Newborn: Less than 0.6 mg/dL
Total:	Birth–5 days: Less than 11.7 mg/dL

Blood Gases

CARBON DIOXIDE, PARTIAL PRESSURE (PCO_2) (B)[1]

Infants:	27–41 mmHg (3.6–5.5 kPa)
Children:	32–48 mmHg (4.3–6.4 kPa)

OXYGEN, PARTIAL PRESSURE (PO_2) (B)[1]

Greater than 1 day:	83–108 mmHg (11–14.4 kPa)

BICARBONATE, ACTUAL (P)[3]

22–29 mmol/L

Key for type of specimen: *S = serum; B = whole blood; P = plasma.*

pH (B)[1]

0–6 months:	7.18–7.50
6–12 months:	7.27–7.49
Children:	7.37–7.43
Adolescents:	7.35–7.41

BASE EXCESS (B)[1]

Infants:	–7 to –1 mmol/L
Children:	–4 to +2 mmol/L
Thereafter:	–3 to +3 mmol/L

OXYGEN SATURATION (B)[1]

Newborns:	85%–90%
Thereafter:	95%–99%

BUN—see Electrolytes, Urea Nitrogen

Coagulation Values[4]

Fibrinogen:	175–400 mg/dL
Partial thromboplastin time, activated (aPTT):	22.1–34.1 seconds
Prothrombin time (PT):	11.2–13.2 seconds
International normalized ratio (INR):	2–3

C-Reactive Protein (CRP) (P, S)[1]

0.08–1.8 mg/L

Creatinine (S, P)[1]

1–7 days:	0.7–1.2 mg/dL
7 days–1 year:	0.2–0.5 mg/dL
1–9 years:	0.2–0.8 mg/dL
10–18 years:	0.5–1.1 mg/dL

Electrolytes[1]

CALCIUM (S, P)

Newborn:	7.9–10.7 mg/dL
Thereafter:	8.7–10.7 mg/dL

CHLORIDE (S, P)

102–112 mmol/L

GLUCOSE, FASTING (S, P)[1]

Newborn:	55–117 mg/dL (3.1–6.4 mmol/L)
After 1 month of age:	70–126 mg/dL (3.9–7 mmol/L)

MAGNESIUM (P, S)

1.6–2.4 mg/dL (0.66–0.99 mmol/L)

OSMOLALITY (S)

280–300 mOsm/kg

PHOSPHORUS, INORGANIC (S, P)

2.8–5.6 mg/dL (0.91–1.8 mmol)

POTASSIUM (S, P)

3.7–5 mmol/L

SODIUM (P, S)

134–143 mmol/L

UREA NITROGEN (S, P)

1–13 years:	5–17 mg/dL (1.8–6 mmol/L)
14–19 years:	8–21 mg/dL (2.9–7.5 mmol/L)

Hematology Values (B)

Values are for children 2 to 12 years.

HEMATOCRIT (HCT)[1]

31.7%–39.8%

HEMOGLOBIN (HGB)[1]

10.2–13.4 g/dL

MEAN CORPUSCULAR HEMOGLOBIN (MCH)[1]

23.7–29.5 pg

MEAN CORPUSCULAR HEMOGLOBIN CONCENTRATION (MCHC)[1]

31.8%–34.9%

MEAN CORPUSCULAR VOLUME (MCV)[1]

71.3–87.6 mm^3

RED BLOOD CELL (RBC)[1]

3.89–5.03 × 10^{12}/L

WHITE BLOOD CELL (WBC)[1]

4.86–11.4 × 10^9/L

DIFFERENTIAL[1]

Neutrophils	22.4%–74.7%
Eosinophils	0%–4.7%
Basophils	0.1%–0.6%
Lymphocytes	18.1%–57.8%
Atypical lymphocytes	2%–4%
Monocytes	4.1%–12.3%

Key for type of specimen: *S = serum; B = whole blood; P = plasma.*

PLATELET COUNT[3]

202–367 × 10^9/L

RETICULOCYTE COUNT[1]

0.82%–1.49%

Erythrocyte Sedimentation Rate (Micro)[4]

1–13 mm/hr

Growth Hormone (P, S)[1]

0–6.9 years:	Less than 13.7 mcg/L
7–10.9 years:	Less than 16.5 mcg/L
11–14.9 years:	Less than 14.5 mcg/L
15–18.9 years:	Less than 13.5 mcg/L

Hemoglobin A_{1c} (B)[1]

Normal: 4%–6%

Hemoglobin Fetal (B)[5]

1–30 days:	2.8%–92%
Decreases to adult levels by 12 months:	0%–0.9%

Iron-Related Values

FERRITIN (P, S)[1]

1–5 years:	6–24 ng/mL
6–9 years:	10–55 ng/mL
10–19 years:	Males: 23–70 ng/mL
	Females: 6–40 ng/mL

IRON (S, P)[1]

1–14 years:	22–136 mcg/dL (4–25 micromol/L)
14–19 years:	34–162 mcg/dL (6–29 micromol/L)

IRON-BINDING CAPACITY (S, P)[1]

1–5 years:	268–441 mcg/dL (48–79 micromol/L)
6–9 years:	240–508 mcg/dL (43–91 micromol/L)
10–19 years:	290–570 mcg/dL (52–102 micromol/L)

Lead (B)[3]

Less than 5 mcg/dL

Lipids (S)[2]

TOTAL CHOLESTEROL

Acceptable:	Less than 170 mg/dL
Elevated:	Greater than 200 mg/dL

HIGH-DENSITY LIPOPROTEIN

Acceptable:	Greater than 45 mg/dL or higher
Low:	Less than 40 mg/dL

LOW-DENSITY LIPOPROTEIN

Acceptable:	Less than 110 mg/dL
High:	130 mg/dL and higher

TRIGLYCERIDES

Acceptable	0–9 years: Less than 75 mg/dL
	10–19 years: Less than 90 mg/dL
High	0–9 years: Greater than 100 mg/dL
	10–19 years: Greater than 130 mg/dL

Thyroid Hormones

THYROID-STIMULATING HORMONE (TSH) (P, S)[1]

(in milli-International Units/L)

Age	Males	Females
1–30 days	0.7–16.1	1.0–13.7
1 month–5 years	0.8–7.5	0.7–8.6
6–18 years	0.6–6.4	0.6–6.2

THYROXINE (T_4) (S, P)[1]

1–5 years:	5–14.45 mcg/dL
6–20 years:	4.4–12.1 mcg/dL

THYROXINE, "FREE" (Free T_4) (S, P)[1]

Under 1 year:	1.3–2.8 ng/dL (16.8–36.1 pmol/L)
1–18 years:	1.3–2.42 ng/mL (16.8–31 pmol/L)

THYROXINE-BINDING GLOBULIN (TBG) (P)[1]

(in mg/L)

Age	Males	Females
Cord blood	19–39	19–39
1–11 months	16–36	17–37
1–9 years	12–28	15–27
10–19 years	14–26	14–30

TRIIODOTHYRONINE (T_3) (S)[1]

1–5 years:	106–203 ng/dL
6–10 years:	104–183 ng/dL
11–14 years:	68–186 ng/dL
15–20 years:	71–175 ng/dL

Normal Value Ranges: Urine

Albumin[4]

Less than 1 mg/dL

Catecholamines (Norepinephrine, Epinephrine)[1]

(in mmol/mol creatinine)

Age	Norepinephrine	Epinephrine
0–24 months	0–0.28	0–0.46
2–4 years	0–0.8	0–0.035
5–9 years	0–0.059	0–0.022
10–19 years	0–0.055	0–0.021

Creatinine[1]

3–8 years:	0.11–0.68 g/24 hr
9–12 years:	0.17–1.41 g/24 hr
13–17 years:	0.29–1.87 g/24 hr
Adults:	0.63–2.5 g/24 hr

Osmolality[4]

500–800 mOsm/kg water

Should be higher than serum osmolality.

Protein[4]

Less than 150 mg/24 hr

Specific Gravity[4]

Birth–2 years:	1.001–1.018
Over 2 years:	1.001–1.03

Normal Value Ranges: Sweat

Electrolytes[1]

Sodium and chloride: under 40 mmol/L

Normal Value Ranges: Cerebrospinal Fluid

Protein[1]

Under 1 month:	15–153 mg/dL
Over 1 month:	15–48 mg/dL

Glucose[1]

All ages: 41–84 mg/dL (60%–80% of blood glucose)

Key for type of specimen: *S = serum; B = whole blood; P = plasma.*

Appendix E
Diagnostic Tests and Procedures

Consider the growth and developmental level of the child when preparing the child for a procedure, and support the child during and after the procedure. See Chapter 11 for more information about preparing a child for procedures. Parents need to complete a signed consent after making sure they have an understanding of the procedure, results, and risk factors. When possible, allow the parents to remain with the child during the procedure.

PROCEDURE, DESCRIPTION, AND PURPOSE	NURSING MANAGEMENT
ACTH Stimulation Test	
A drug, metyrapone, is administered to block the production of cortisol. In persons with pituitary insufficiency, the ACTH level does not increase as expected.	• Phenytoin and estrogen compounds interfere with the test results. • Contact the laboratory for timing of the blood specimens to be collected.
ACTH Suppression Test	
Dexamethosone, a potent corticosteroid, is administered to suppress the pituitary and ACTH production. In cases of Cushing syndrome, high levels of serum cortisol continue to be produced.	• Administer dexamethosone in the dose and at the time prescribed. • Contact the laboratory for timing of the blood specimens to be collected. A plastic tube is used rather than glass. Urine may also be collected to test the level of cortisol.
Arteriography/Angiogram	
A contrast dye is injected to allow visualization of blood vessels. Useful in evaluating patency of blood vessels and blood flow to parts of the body and in identifying abnormal vasculature.	• Obtain history of hypersensitivity to iodine, seafood, or radiographic contrast dye. Antihistamines and/or steroids may be prescribed if allergy is suspected. • Administer sedation as prescribed, and follow assessment guidelines to monitor the child during and after the procedure; assess for vasovagal and allergic reactions. • Tell the child to expect a warm, flushing feeling that could last a few minutes.
Arthrogram	
After a local anesthetic, a needle is inserted into a joint (e.g., knee or shoulder). Samples of joint fluid may be aspirated, and then air or contrast medium is injected into the joint cavity. The joint is moved to spread the dye. Radiographs are taken with the joint in various positions to detect injuries to cartilage or ligaments and to visualize the joint capsule.	• Prepare the child and family for the procedure. • Local anesthesia is often used with general anesthesia for very young children. Support the child when the local anesthetic is inserted. • Rest, ice on the joint, elevation, and an analgesic may be needed for discomfort after the procedure.
Barium or Contrast Enema	
Barium or barium and air are administered via a tube through the rectum to the colon. The large intestine is visualized to detect any abnormalities. Fluoroscopy is used to monitor the process and radiographs are taken.	• Give parents preprocedure instructions regarding diet, laxatives, and/or enemas so that the colon is clear. • Prepare the child and parents for the procedure and to expect the sensation of fluid entering the rectum. Tell the child of the need to not have a bowel movement until told it is okay to do so. • Ensure that the child holds still while the radiographs are taken.
Biopsy	
Removal and examination of tissue from the body organs or skin to detect malignancies or the presence of disease. Biopsies can be obtained in several ways: • Surgical excision at tissue site • Needle aspiration at tissue site, with or without ultrasound • Needle insertion into skin • Brush method, scraping cells and tissue with stiff bristles as is done with a Pap smear • Punch, using an instrument to excise a small area of tissue	• Prepare necessary instruments and specimen containers. Assist with preparation of biopsy site. • Monitor the child receiving sedation and analgesia according to protocol. • Ensure that the child remains still during the procedure. • Apply dressing, if appropriate, to the site after the procedure. • Label specimens accurately and arrange for specimen transport as recommended. • Teach family to care for wound and to monitor site for infection.
Bone Marrow Aspiration	
Marrow is removed from pelvic or iliac crest bones through a large gauge needle with a syringe used for aspiration. The test is diagnostic for leukemia, metastatic tumors, and some anemias, and it tests for response to treatment. Marrow may also be harvested for transplant.	• The child is usually given anesthesia, or sedation and analgesia. Follow monitoring guidelines during and after the procedure. • The site is prepped with a cleansing agent according to agency protocol. • Positioning is determined by the site used (e.g., side-lying for the iliac crest). • After the procedure, maintain the child on bed rest for at least 1 hour. • Mild analgesics are provided for pain at the harvest site.

PROCEDURE, DESCRIPTION, AND PURPOSE	NURSING MANAGEMENT
Bronchoscopy	
A flexible fiber-optic bronchoscope is used to visualize the trachea and bronchi to identify and extract foreign objects in the airway, or for a biopsy.	• Maintain NPO status preprocedure according to agency guidelines. • The child will often be sedated for the procedure; if the child is not sedated, a local anesthetic spray is used prior to passing the bronchoscope. Monitor the child according to agency guidelines. • Monitor vital signs per protocol postprocedure. Resume oral feedings as prescribed.
Cardiac Catheterization	
A radiopaque catheter is passed through a large vein or artery in an arm or leg to the heart. It is then threaded to the heart chambers or coronary arteries, or both, guided by fluoroscopy. The procedure enables precise measurement of oxygen saturation within the heart's chambers and great arteries and pressure gradients in the pulmonary vessels or heart chambers. This helps assess for: • Congenital heart defects • Cardiac valvular disease • Coronary artery disease • Evaluation of artificial valves Other purposes of cardiac catheterization include heart muscle biopsy, tissue sampling for heart transplant rejection, or radiofrequency ablation for a heart rhythm disturbance.	• Preparation includes discontinuation of anticoagulant therapy a week prior to the test and no food or fluid 6 to 8 hours preprocedure (may be a shorter interval for infants). Have the child void. • Prepare the child about the equipment to be used and sensations that will be felt. • Obtain history of hypersensitivity to iodine, seafood, or radiographic contrast dye. Antihistamines and/or steroids may be ordered if allergy is suspected. Assess for allergic reaction during procedure. • An IV is started for sedation administration, and to provide access for emergency drugs if needed. • ECG leads are applied to the chest to monitor heart activity. Baseline vital signs, extremity circulation, and pulses are assessed and documented. Vital signs, heart rhythm, and the pulse strength and neurovascular assessment of the affected extremity are monitored according to agency protocol. • See Chapter 21 for nursing management after the procedure.
Computed Tomography (CT)	
The CT scan is a radiographic procedure that examines body sections from 360 degrees, producing cross-section images that build into a two-dimensional image of any body structure. It may be performed with or without contrast dye. Multislice CT is performed with a greater number of images obtained simultaneously for a more rapid procedure so that moving organs are not blurred. CT is used to screen for head, liver, abdominal, and renal lesions; tumors; edema; abscesses; and bone destruction. It is also used to locate foreign objects in soft tissue, such as the eye.	• If contrast dye is required, the infant or child may be NPO. CT must be performed 4 days after any other barium studies of abdomen. • If contrast dye is to be used, obtain a history about any hypersensitivity to iodine, seafood, or radiographic contrast dye. If allergy is suspected, antihistamines and/or steroids may be ordered prior to procedure. Assess for allergic reaction during procedure. • Prepare child for the procedure by describing the equipment, noises, and other expected sensations, and how the child can help during the procedure by not moving. • If sedation is ordered for infants and small children to keep them still, monitor them according to protocol. • If contrast dye is used, encourage fluids after the procedure.
Cultures	
Cultures are taken to isolate and identify microorganisms causing infection, and often to identify the specific antibiotics to which the organisms are sensitive. Cultures commonly used with children include: blood, throat, sputum, stool, wound, urine, and cerebrospinal fluid.	• Collect culture specimens before administering new antimicrobials to prevent false results. List any antimicrobials given on laboratory slip. • Send all specimens immediately to the laboratory, or refrigerate the specimen. • Use strict aseptic technique to handle the specimen. Keep lids on sterile specimen containers.
Cystoscopy	
A flexible fiber-optic scope is inserted through the urethra into the bladder to inspect the interior urethra and bladder for inflammation, tumors, stones, or structural abnormalities. The procedure may be done simultaneously with a voiding cystourethrogram (see Voiding cystourethrogram later in this table).	• Keep infants and children NPO prior to the study if sedation will be used. • Administer sedation and/or analgesia as prescribed, and monitor the child according to protocol. • Encourage fluids after the procedure to detect problems with voiding. • Inform the child and parents that dysuria and frequency may occur for a short time following the procedure.
Dual Energy X-ray Absorptiometry (DEXA)	
DEXA is radiographic procedure emitting two photon energy beams used to measures bone mineral density in children at risk for glucocorticoid-induced osteoporosis.	• Identify factors increasing a child's risk for osteoporosis or skeletal problems. • Explain the procedure and equipment to be used to the child and parents. • Inform the child of the need to not move, and let the child know the test does not cause pain.
Echocardiography	
An ultrasound study of the heart used to identify the heart size, structure, pattern of movement, hemodynamics, valvular disease, blood flow, and blood flow disturbances. The ultrasound probe (transducer) is held over the chest (transthoracic) or inserted through the esophagus (transesophageal) to send an ultrasound beam to the tissues. The reflected sound waves are then transformed into scans, graphs, or sounds (Doppler).	• Explain the procedure to the parents and child. Inform the child of the need to hold still for the procedure. • Inform the child that patches and a gel will be applied to the skin and a transducer will move over the area with some pressure, but that the test should cause no pain.

PROCEDURE, DESCRIPTION, AND PURPOSE	NURSING MANAGEMENT
Electrocardiography (ECG or EKG) and Ambulatory Electrocardiography	
An (ECG) records the electrical impulses of the heart via electrodes and a galvanometer (ECG machine). Eight electrodes are placed on the chest and an electrode is placed on each extremity. The lead selector is turned to read the 12 standard leads. A Holter monitor may be attached to capture ambulatory ECG readings over a 24-hour period. An ECG is used to detect cardiac arrhythmias, identify electrolyte imbalances, or to monitor ECG changes during an exercise or stress test.	• Obtain list of current medications and when they were last taken. • Inform the child that patches will be applied to the chest, arms, and legs. Then wires will be attached to the patches. Tell the child that the test causes no pain. • Ask the child to hold still for a brief time. A pacifier or bottle may help the infant be still. • Encourage the child with a Holter to engage in usual activities, but no swimming or bathing in a tub or shower is allowed until electrodes are removed. • Ask the parents of the child wearing a Holter monitor to keep a diary of any events or emotional stress that cause symptoms. A daily schedule of sleep, eating, exercise, and other activities may be requested.
Electroencephalogram (EEG)	
Approximately 20 electrodes are applied to the scalp to record cerebral cortex electrical activity over 1 to 2 hours. In some cases an EEG is performed when the child is asleep. An EEG is used to identify the potential for seizures, to determine brain death, and to detect other abnormalities such as a tumor, abscess, or intracranial hemorrhage.	• Inform the parents and child about all medications and other substance (e.g., cola, tea, or coffee) to withhold for 24 to 48 hours. • Ensure that the hair is clean, and dry, and no hair products (e.g., oil, gel, spray) have been applied. • Do not permit infants or children to nap before the test. • Explain that the procedure is not painful as electrodes are applied. • Explain that washing the child's hair will remove the electrode gel.
Electromyography (EMG)	
Needle electrodes are inserted into skeletal muscles, and muscle activity is measured during rest, voluntary activity, and electrical stimulation. The test is useful in assisting with diagnosis of muscular dystrophy and to differentiate muscle diseases and lower motor neuron neuropathies such as those caused by hypothyroidism or diabetes.	• Be alert to medications (muscle relaxants, antiholinergics, and cholinergics) or caffeine use that could affect EMG results, and whether they should be withheld. • Inform the child that there may be slight pain when the needle electrodes are inserted. Support the child with age-appropriate relaxation techniques or distraction techniques. If pain persists, inform technician. Pain may cause false reports. • Administer analgesic as needed for residual pain.
Esophagogastroduodenoscopy/Esophagastroscopy	
A flexible fiber-optic endoscope is used to visualize the internal structures of the esophagus, stomach, and duodenum. This procedure is also used to collect cytology specimens and to confirm gastrointestinal pathology (e.g., tumors, ulcerations, bleeding).	• Keep the child NPO prior to the procedure. • Administer sedation as prescribed and monitor the child during and postprocedure according to protocol. • Inform children that they may be asked to swallow and may feel some pressure when the endoscope is inserted. • Resume oral feedings as prescribed. Explain that some burping may occur, which helps remove air inserted to visualize the GI tract.
Evoked Potential	
A child who is awake is monitored by electrodes measuring brain (e.g., electroencephalogram) and related muscle activity. The baseline of electrical activity obtained is then used during later surgery, such as a spinal fusion for scoliosis, in order to monitor innervation to muscle groups and avoid injury to the spinal cord during the surgical procedure.	• Prepare the child for the procedure, including the size of equipment, sounds, and time it will take. • Assist the child to relax with quiet music during the test.
Exercise Testing	
A test performed with a treadmill or stationary bicycle to evaluate exercise tolerance. ECG leads, a blood pressure cuff, and sometimes an oxygen consumption monitor are attached. Acceleration and pitch of the treadmill or bicycle are increased at intervals until the patient is fatigued, symptomatic, or a predetermined endpoint is reached. An ECG recording with a controlled activity increase helps identify significant cardiac compensation or inadequate cardiac output.	• Prepare the adolescent for the test, what to expect, and that the test can be stopped at any time. • Instruct the adolescent to report vertigo, extreme shortness of breath, chest pain, and excessive fatigue. • Ensure that the adolescent understands that the test is of greater value when the exercise continues until the predetermined stopping level is reached. • Take baseline vital sign measurements prior to the exercise and throughout according to agency guidelines.
GI Series	
Upper GI and small bowel series are fluoroscopic and radiographic examinations of the esophagus, stomach, and small intestine as ingested oral barium or water-soluble contrast agent passes through the digestive tract. This series identifies ulcers; gastroesophageal reflux; polyps, tumors, or hiatal hernias in the GI tract; pyloric stenosis; and foreign bodies, varices, or strictures.	• Keep child NPO after midnight or for the number of hours according to agency guidelines. A low-residue diet may be ordered for the night before the test. • Withhold medications as ordered. • Record vital signs; note epigastric pain or discomfort. • Inform child that all the liquid must be swallowed, but that the test will not cause pain or discomfort. • Inform the child that the room will be dark and the table on which the child is lying may be tilted. • Inform parents that the stool will be light colored after the test.

PROCEDURE, DESCRIPTION, AND PURPOSE	NURSING MANAGEMENT
Hyperoxitest Arterial blood is collected before and at least 10 minutes after giving the infant 100% oxygen to see how the child's PO_2 level responds to the oxygen. Differences between the arterial blood gas levels when an infant has central cyanosis help distinguish between cardiac disease and pulmonary disease (Park, 2014).	• Follow guidelines for arterial blood collection from the upper right side of the body. • Administer oxygen through a plastic hood for at least 10 minutes to replace all alveolar air with oxygen.
Intraesophageal pH Probe Monitoring A probe is placed in the distal esophagus for 24 hours to detect pH changes below 4. The pH is measured and recorded every 4 to 8 seconds. The test determines how frequently stomach acid enters the esophagus and how long it stays there. It is used to diagnose gastroesophageal reflux disease and to evaluate atypical symptoms such as apnea, stridor, or cough.	• Inform the family of medications that must be withheld before and during the test (e.g., antacids, H2 inhibitors, proton pump inhibitors). • Prevent the infant or child from inadvertent removal of the probe. Use soft mittens on the child's hands if necessary. • Monitor and record pH measurements per protocol. • Instruct parents to keep a diary of the child's activities while probe is in place (e.g., feeding or sleeping).
Intravenous Pyelogram A contrast dye is administered by IV and excreted by the urinary system. A series of radiographs is taken at various intervals over an hour to evaluate the entire urinary system, including the kidney cortex, kidney pelvis, ureters, and bladder. A post-void radiograph is taken to see how well the bladder empties. The test is used to diagnose structural defects and tumors in the urinary system.	• Assess for potential allergy to the contrast dye. An antihistamine or corticosteroid may be given to children with a potential allergy. Monitor the child carefully for an allergic reaction. • Obtain a serum creatinine and BUN prior to the test to assess renal function. • Follow orders for an NPO or clear liquid diet prior to the study, in addition to the cleansing enema the morning of the test. • Encourage fluids after the procedure to flush out the contrast media, and monitor urinary output.
Lumbar Puncture A lumbar puncture is performed at the L3–L4 or L4–L5 level to obtain a specimen of cerebrospinal fluid (CSF) and to measure the CSF pressure. CSF is cultured and analyzed for glucose and protein content, and the number of lymphocytes present.	• Obtain a blood glucose level prior to the test for comparison with the CSF glucose level. • Hold the infant or child in knee-chest position and keep the child still during the procedure. • Label the tubes of CSF obtained by numerical sequence. • Assess breathing and any changes in neurological function during the test. • Administer analgesics as ordered for headache.
Magnetic Resonance Imaging (MRI) A radiographic examination that uses a large magnet to produce a magnetic field and radio waves to produce detailed images without ionizing radiation. The MRI scanner is a large, doughnut-shaped cylinder and the child lies on a table in the cylinder. An intravenous contrast dye often used. An MRI provides detailed images of internal organ structure, blood flow patterns, and abnormalities in soft tissues.	• Prepare the child for loud sounds, the size of the equipment, and the tunnel. Cardiorespiratory leads are often placed on the chest when contrast dye is used. • Assess the child for potential allergy to the contrast dye. An antihistamine or corticosteroid may be ordered if the child is at risk for allergy. Monitor the child for allergy during the procedure. • Carefully check for and remove all metal objects from the body. Only preapproved medical equipment can be in the room. • Sedation may be needed to keep the infant or child still. Headphones with music may help older children to cooperate. Monitor the child according to agency guidelines. Commonly, the examiner can talk with the child via a speaker system to provide information and reassurance.
Nuclear Scan or Radionuclide Imaging A radionuclide (an unstable radioisotope that decays or disintegrates, emitting radiation) is given by mouth or IV, which concentrates in certain parts of the body. Scintillation (gamma) camera detectors are used to create a two-dimensional image of an organ in gray tones or color that is sent to a computer. The scans may be taken in several minutes, hours, or 24 hours later. The test may identify a functional (rather than a structural) problem in the bone, brain, gastrointestinal tract, or kidney, or a thyroid scan may diagnose hyperthyroidism or hypothyroidism.	• Explain the procedure to the parents and child. Inform them that the amount of radiation received from radionuclide imaging is usually less than that received from a radiograph, and that there will be no discomfort. • The child may be NPO for several hours before the initial scan. • The nurse should wear two pairs of disposable gloves when in direct contact with the child's wastes for several hours. Follow agency guidelines for handling waste products. • Inform the child and family that radionuclide is excreted from the body in 6 to 24 hours. Ask the child and family to flush the toilet 3 times after voiding. Ask parents to schedule the test when airline travel is not planned for several days as the radioactive substance may set off security scanners.
Polysomnography (Sleep Study) Electrodes are attached to the head and chest, and a pulse oximeter is used. Recordings of brain activity, eye movement, apnea episodes, oxygen desaturation, and sleep disturbances are taken during sleep over an 8-hour period. The test is used to identify apnea during sleep and to determine the cause of sleep disorders.	• Instruct family to keep sleep log 1 to 2 weeks prior to sleep studies, including notes about snoring and sleepiness during the day. Review the sleep log. • Instruct patient/family to avoid caffeine products, sedatives, and naps for 1 to 2 days prior to testing. • Obtain a history related to medications, head injury, headache, and seizures. Caffeine and sedatives may be withheld. • Explain the procedure to the parents and child. • Monitor vital signs and observe for respiratory distress during the test.

PROCEDURE, DESCRIPTION, AND PURPOSE	NURSING MANAGEMENT
Positron Emission Tomography (PET) Scan and Single Photon Emission Computed Tomography (SPECT)	
PET alone or in combination with CT uses an intravenous radioisotope to measure emission of positive electrons in body organs, such as the brain or heart, or detect tumors and metastases. PET is effective in evaluating cerebral blood flow and myocardial perfusion as well as detecting recurrent cancer. SPECT is used to measure blood perfusion in the brain and evaluate central nervous system disorders.	• Inform the child and family if food and fluids must be withheld. • Prepare the child for the procedure in order to reduce anxiety. • Start two IVs, one for the radioisotope and the other for serial blood gases. • Monitor vital signs. • Assess for potential allergies to the radioisotope medium.
Pulmonary Function Tests (Spirometry)	
The patient breathes into a spirometer connected to a computer, and the results are analyzed. The vital capacity (maximum amount of air that can be expired after a normal inspiration) and forced expiratory volume (FEV), the percentage of air expired at 1, 2, and 3 seconds, can be calculated. Pulmonary function tests are used to assess pulmonary function and to identify the severity of obstructive airway disease.	• Obtain a list of any bronchodilators and steroids the child is taking. • Record child's age, gender, height, weight, and vital signs. • Assess for signs and symptoms of respiratory distress. • Explain the purpose of the tests and procedures. • Help the child practice breathing patterns required for the test. • Take two readings and average the values; compare to expected values for age, gender, and height.
Pulse Oximetry	
Pulse oximetry provides an estimate of the hemoglobin saturated by oxygen, measured percutaneously (SpO_2). It serves as an alternate to the direct measurement of PaO_2 (SaO_2) through arterial blood gas analysis.	• Explain that the sensor needs to be over a finger or nailbed. • Monitor the skin under the sensor regularly if it is kept in place for a constant measurement.
Radiograph (X-ray)	
The most common form of imaging, radiographs use electromagnetic radiation to obtain images of body structures on film for diagnostic purposes. Radiographs are commonly used to detect abnormalities in the size, structure, and shape of bone and body structures, or to detect abnormalities of the chest, such as air trapping in the alveoli (hyperinflation), consolidation of lung tissue (pneumonia), or lung collapse.	• Determine if any other radiographic procedures have been performed recently, as the contrast dye used may distort radiograph images. • Explain the procedure to the parents and child and the need for a lead apron. Explain that one or more films will be taken in about 5 to 10 minutes. Explain that modern equipment decreases radiation exposure. • Prepare the child. Have the child practice holding still and holding a breath in preparation for the test.
Sweat Chloride Test	
Gel pads containing pilocarpine are placed on the child's arms. A small electrode is attached to the pads to stimulate sweating until enough sweat is collected. The arms are covered with plastic. Sweat is collected and analyzed for the concentration of chloride and osmolality. The test is used to diagnose cystic fibrosis.	• Explain the purpose of the test to the parents and child. • Explain the need for the child to keep the plastic covering over the lower arms in place for the duration of test (about 30 minutes).
Tympanogram	
The procedure provides an estimate of middle ear pressure and an indirect measure of tympanic membrane movement. This helps identify the presence of fluid accumulation in the middle ear.	• Explain the procedure to the parents and child. The young child should be held still by a parent. • Insert the earpiece with the probe into the auditory canal until the canal is sealed tightly. • Use the machine according to the manufacturer's instructions. • Repeat the test in the other ear.
Ultrasound	
An ultrasound probe (transducer) is held over the skin or body cavity to transmit ultrasound waves to the tissues and receives deflected sound waves as they bounce off various body structures. The computer transforms the deflected sound waves into two-dimensional electronic scans or audible sounds (Doppler). Ultrasound is usually a noninvasive procedure used to detect tissue abnormalities.	• Explain the procedure to the parents and child. Inform them that the procedure is painless, and there is no exposure to radiation. • Maintain NPO status preprocedure for abdominal studies. • Confirm the child has not received any tests that will interfere with results (e.g., upper GI series). • Instruct the child to remain still during the procedure.
Voiding Cystourethrogram or Radionuclide Cystography	
A cystoscopy procedure is combined with a radionucleotide scan to examine bladder structure and function, urethral anatomy, and bladder masses. The test may detect vesicoureteral reflux.	• Assess for potential allergies to radioisotope medium. • Explain catheterization to the child and that the bladder will be filled. • Provide coaching strategies for parents accompanying the child to help the child cooperate and cope during the test. • Encourage fluids after the procedure to flush out the contrast media.

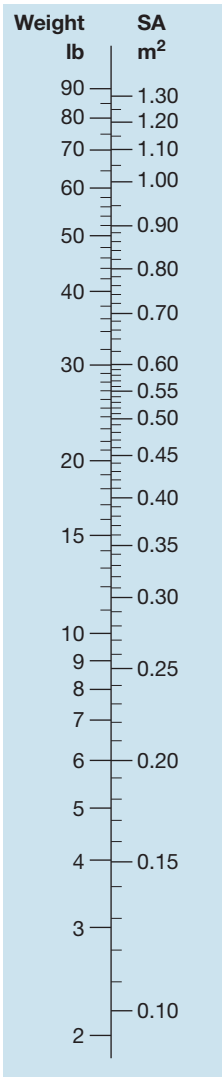
Appendix F
Body Surface Area Nomogram

Nomogram for child with proportional height and weight



Nomogram for child with varied height and weight percentiles

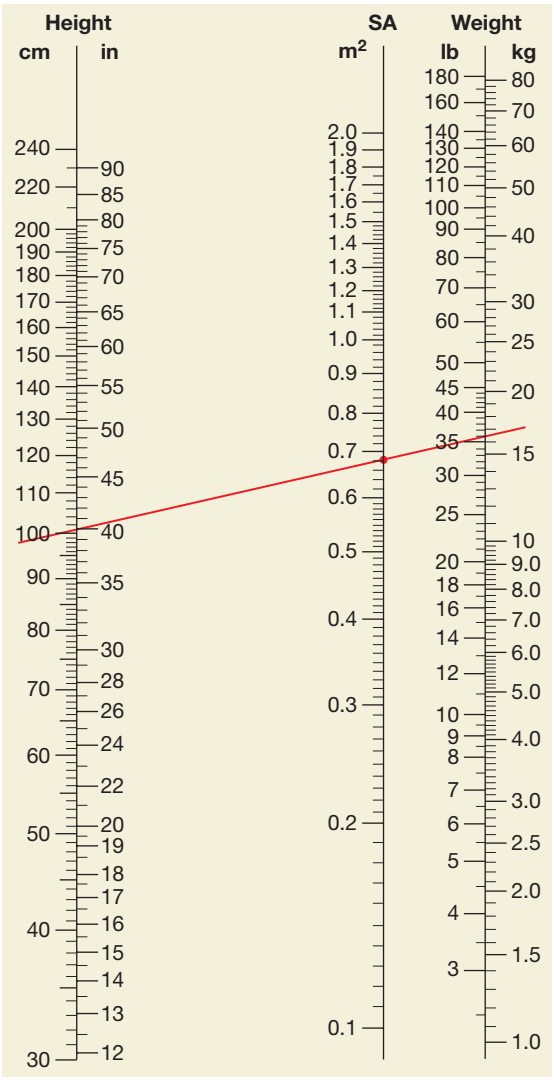


Figure F–1 The proportion between height and weight in children is different from the proportion in adults. These differences are most manifest in newborns, infants, and young children. Therefore, dosages of drugs that have been established for adults cannot simply be reduced and, correspondingly, be safe for young children. Weight is used as a better method of calculating drug dosage in children and is used when medications have a dose of drug recommended in mg/kg.

Weight alone, however, is not always accurate as a method of calculating a drug dosage for a child. Another more accurate method is that of body surface area (BSA). BSA is a relationship of height to weight and is measured in square meters. It increases about 7 times from birth to adulthood. It is a good reflection of many physiologic processes significant in metabolizing, transporting, and eliminating drugs, such as metabolic rate, extracellular fluid and total fluid volumes, cardiac output, and glomerular filtration rate. BSA is calculated by the formula:

$$\text{Surface area}(m^2) = \sqrt{\frac{\text{height(cm)} \times \text{weight(kg)}}{3600}}$$

A nomogram or graph has been developed to calculate BSA quickly and accurately. The nomogram on the left in Figure F–1 can be used when a child has height and weight in proportion, or in the same percentile range. (See Chapter 14 for a description of growth measurements and percentiles.) When the percentiles for height and weight differ, the nomogram on the right can be used. To calculate a child's BSA, draw a straight line from the height to the weight. The point at which the line intersects the surface area (SA) column is the BSA (measured in square meters, m^2). Medications that are prescribed using the BSA system are dosed in mg/m^2.

Appendix G
Conversions and Equivalents

Temperature Conversion

(Fahrenheit temperature – 32) × 5/9 = Centigrade temperature
(Centigrade temperature × 9/5) + 32 = Fahrenheit temperature

Selected Conversion to Metric Measures

KNOWN VALUE	MULTIPLY BY	TO FIND

Glossary

A

Acanthosis nigricans Hyperpigmentation and thickening of the skin associated with chronic hyperinsulinemia.

Accommodation The process of changing one's cognitive structures to include data from recent experiences.

Accommodations Services or special assistance provided in the school setting to ensure that a student with a physical or mental impairment has access to an appropriate education and is able to participate as fully as possible in school activities.

Acculturation The process of modifying one's culture to fit within the new or dominant culture.

Acellular pertussis vaccine A vaccine that uses pertussis proteins rather than the whole cell to stimulate active immunity.

Acidemia Decreased blood pH.

Acidosis Condition caused by excess acid in the blood.

Acquired immunity Humoral (antibody-mediated) and cell-mediated immunity that is not fully developed until a child is about 6 years of age.

Active immunity Stimulation of antibody production without causing clinical disease; antibody development for specific infections through immunization or exposure to the natural disease.

Acute pain Sudden pain of short duration, associated with a tissue-damaging stimulus.

Adaptation phase Period during a crisis when the child and family meet the challenge and use resources effectively.

Adaptive functioning The ability of an individual to meet the standards expected for his or her age by his or her cultural group.

Adherence The extent to which a client or parent follows recommended care for the health problem.

Adjustment phase Period just after a family is confronted by a crisis; characterized by disorganization and unsuccessful attempts to deal with the problem.

Adoption A legal relationship between the child and parents not related by birth in which the adoptive parents assume all legal and financial responsibility for the child.

Adrenarche The development of pubic and axillary sexual hair.

Advance directives A client's living will or appointed durable power of attorney for healthcare decisions.

Adventitious sounds Breath sounds that are not normally heard, such as wheezes, crackles, and rhonchi.

Advocacy Acting to safeguard and advance the interests of another.

Affect Outward manifestation of feeling or emotion; the tone of a person's reaction or response to people or events.

Agoraphobia Anxiety of being in places or situations from which escape may be difficult or embarrassing, or in which help may not be available.

Air hunger The most severe form of dyspnea, when a person or child looks panicked, gasps for breath, and sits upright.

Airway resistance The effort or force needed to move oxygen through the trachea to the lungs.

Alkalemia Increased blood pH.

Alkalosis Condition caused by too little acid in the blood.

Alleles Different forms of a gene or DNA occupying the same place on a pair of chromosomes; an allele for each gene is inherited from each parent.

Allergen An antigen capable of inducing hypersensitivity.

Allergy An abnormal or altered reaction to an antigen.

Allogeneic transplantation A procedure in which a donor (often a sibling [related] or sometimes someone unrelated) with a compatible human leukocyte antigen (HLA) gives bone marrow to a child with an immune or hematologic disease needing restoration of normal cells.

Allograft Cadaver skin from a skin bank used to temporarily cover a full-thickness burn.

Allow natural death (AND) Continuation of ongoing care, managing pain, and choosing not to initiate cardiopulmonary resuscitation if the child stops breathing or the heart stops beating.

Alternative therapy A substance or procedure that is used in place of conventional medicine.

Amenorrhea Lack of menstruation.

Anemia Reduction in the number of red blood cells, the quantity of hemoglobin, and the volume of packed red cells per 100 mL of blood to below-normal levels.

Aneuploidy An increase or decrease in chromosome number that is the result of an error during cell division, most often when nondisjunction occurs during meiosis.

Animal-assisted therapy A form of therapy used in hospitals and units in which specially trained animals (commonly dogs) provide diversion, distraction, comfort, and relaxation during health care.

Anthropometric measurement The term used to refer to growth assessment of various parts of the body.

Antibodies Proteins capable of responding to specific infectious agents (antigens).

Anticipation The tendency for certain genetic disorders to display earlier onset and increased severity in successive generations of a family.

Anticipatory guidance The process of understanding upcoming developmental needs and then teaching caretakers to meet those needs.

Antigen A foreign substance that triggers an immune system response.

Anuria Absence of urine output.

Apical impulse Also called the point of maximum intensity; is located where the left ventricle taps the chest wall during contraction. The apical impulse is usually seen in thin children.

Apnea Cessation of respiration lasting longer than 20 seconds.

Apoptosis Programmed cell death. When the cell "realizes" something is wrong and destroys itself.

Areflexia A lack of reflex response to verbal, sensory, or pain stimulation.

Arrhythmias Abnormal heart rhythms or dysrhythmias.

Asplenia Loss of the spleen due to surgery or nonfunctioning due to sickle cell disease.

Assent Voluntary agreement to accept treatment or to participate in a research project.

Assimilation The process of incorporating new experiences into an individual's cognitive awareness; the process of incorporating traits of the new culture within one's practice.

Assistive technology Any item, equipment, or product customized for use to promote the functional capabilities and independence of an individual with disabilities.

Association A group of abnormalities of unknown cause that is seen together more often than would be expected by chance.

Associative play A type of play that emerges in preschool years when children interact with one another, engaging in similar activities and participating in groups.

Atopy A hereditary allergic tendency.

Audiography A test used to assess hearing in which sounds of various pitches and intensity are presented to children through earphones.

Aura A visual, auditory, taste, or motor sensation that gives warning of an impending seizure or migraine headache.

Auscultation The technique of listening to sounds produced by the airway, lungs, stomach, heart, and blood vessels to identify their characteristics. Auscultation is usually performed with the stethoscope to enhance the sounds heard.

Autograft Use of healthy skin taken from a nonburned area of the child's body to cover an area with a full-thickness burn.

Autologous transplantation A procedure in which the child's own marrow is taken, treated, stored, and reinfused after the child has received chemotherapy.

Automatism Unusual body movement without purpose (e.g., lip smacking, lip chewing, and sucking).

Autonomic dysreflexia Condition in which hypertension, bradycardia, severe headaches, pallor below and flushing above the level of the spinal cord lesion, and seizures occur due to an impaired autonomic nervous system, triggered by simultaneous sympathetic and parasympathetic activity.

Autosome Chromosome other than the sex chromosome.

Azotemia Accumulation of nitrogenous wastes in the blood.

B

Behavior modification A therapeutic technique used to reinforce desirable behaviors, helping the child replace maladaptive behaviors with more appropriate ones.

Benign Describing a growth that does not endanger life or health.

Binge eating A compulsion to consume large quantities of food in a short period of time.

Binocularity Ability of the eyes to function together.

Biotherapy A treatment that uses and/or enhances the body's abilities to fight disease, particularly by using biologic agents to promote an immune response.

Bisexual Sexual attraction to both men and women.

Body fluid Body water that has substances (solutes) dissolved in it.

Body image The idea that one forms about one's body.

Body mass index (BMI) A calculation (kilograms of weight/m2 of height) used to determine the proportion between a child's or adult's height and weight.

Bone age Stage of bone ossification.

Brain death The irreversible cessation of all functions of the brain, including the cerebral cortex and brainstem.

Breakthrough pain Pain that emerges as the pain medication wears off, resulting in the loss of pain control.

Bronchiectasis A persistent abnormal dilation of the bronchi.

Bronchophony Change in vocal resonance in the presence of a lung consolidation, in which there is increased intensity and clarity of sounds while the words remain indistinct.

Buffer Related acid–base pair that gives up or takes up hydrogen ions as needed to prevent large changes in the pH of a solution; a compound that binds hydrogen ions when their concentration rises and releases them when their concentration falls..

Bullying Repeatedly aggressive behavior intended to cause physical or emotional harm that exists in a relationship with an imbalance of power.

C

Carcinogens Chemicals or processes that, when combined with genetic traits and in interaction with one another, cause cancer.

Cardiac output Volume of blood ejected from the left ventricle each minute.

Cardiomegaly Enlargement (hypertrophy) of the heart muscle.

Care coordination The process of planning and integrating healthcare services among providers in an effort to achieve and promote good health in the child.

Caregiver burden The unrelenting pressure and anxiety related to providing daily care to a child with disabilities while meeting other family obligations.

Carrier Any individual who carries a single copy of an altered gene or mutation for a recessive condition on one chromosome of a chromosome pair and an unaltered form of that gene on the other chromosome; a carrier generally is not affected by the gene alteration; on the average, each person in the general population is a carrier of five or six gene mutations for recessive disorders.

Case management A process that involves the assessment, planning, facilitation, and delivery of healthcare services, which includes healthcare options by the interprofessional team to promote quality and cost effectiveness of care.

Case manager Person who coordinates health care to prevent gaps or overlaps.

Cell The basic unit of life and the working unit of all living systems.

Cephalocaudal development The process by which development proceeds from the head downward through the body and toward the feet.

Cerebral edema An increase in intracellular and extracellular fluid in the brain that results from anoxia, vasodilation, or vascular stasis.

Cerebral perfusion pressure Amount of pressure needed to ensure that adequate oxygen and nutrients are delivered by the blood to the brain.

Chelation A reaction in which an organic compound, containing carbonyl (CO) and hydroxyl (OH) groups, coordinates with a metal to form a firmly bound ringlike structure.

Chemotherapy Treatment to combat cancer that involves drugs taken orally, intravenously, intrathecally, or by injection, which kill both normal and cancerous cells.

Child-life specialist Trained professional who plans age-appropriate therapeutic activities for hospitalized children.

Child sexual abuse The exploitation of a child for the sexual gratification of an adult or older child.

Children with special healthcare needs (CSHCN) Children who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally.

Cholestasis Disruption of bile flow.

Chondrolysis The breaking down and absorption of cartilage.

Chronic condition A health condition that lasts or is expected to last 3 months or more.

Chronic pain Persistent pain lasting longer than 3 months, generally associated with a prolonged disease process.

Chronic vomiting Low-grade, nearly daily emesis.

Chvostek sign Contraction of facial muscles after tapping the facial nerve just anterior to the parotid gland.

Circumferential Injury completely surrounding the thorax or an extremity.

Clinical practice guideline A consensus of evidence-based and expert opinion statements about the care for a specific diagnosis used to assist the interprofessional team of healthcare providers to make decisions about the appropriate care of a child with that condition.

Clinical reasoning The analytical process used when assessing client cues and information, synthesizing that information and applying it to understand a child's or family's problem or concern, and then using the nursing process to plan and evaluate the child's care.

Clonic Alternating muscular contraction and relaxation; often used to describe seizure activity.

Clubbing A widening of the nail bed with an increased angle between the proximal nail fold and nail.

Cognition The change in thought, intelligence, and language that occurs from the mutual interaction of brain maturation with life experiences.

Cognitive therapy A therapeutic approach that attempts to help the person recognize automatic thought patterns that lead to unpleasant feelings (automatic negative thinking).

Collaborative practice A comprehensive model of health care that uses an interprofessional team of health professionals to provide high-quality, cost-effective care.

Coloboma A keyhole-shaped pupil caused by a notch in the iris.

Coma State of unconsciousness in which the child cannot be aroused, even by powerful stimuli.

Comedone A plug of sebaceous and keratin material in a hair follicle; commonly known as *whiteheads* and *blackheads.*

Communicable disease An illness that is transmitted directly or indirectly from one person to another.

Community assessment A process of compiling data about a community's health status and resources for the purpose of developing a public health plan to address the priority health needs of a target population within that community.

Compartment syndrome A condition of increased pressure in a limited space that compromises circulation and tissue function.

Complementary therapy Any procedure or product that is used as an adjunct to conventional medical treatment.

Compliance Amount of expansion the ventricles can achieve to increase stroke volume.

Conductive hearing loss Hearing loss caused by inadequate conduction of sound from the outer to the middle ear.

Confidentiality An agreement between a client and a provider that information discussed during the healthcare encounter will not be shared without the client's permission.

Conjugated forms An altered organism is joined with another substance in a vaccine to increase the immune response to the vaccine.

Consanguinity Related by having a common ancestor; close blood relationship.

Consciousness The responsiveness to or awareness of sensory stimuli, including the ability to process the data and respond either verbally or physically.

Conservation The knowledge that matter is not changed when its form is altered.

Constipation Difficult and infrequent defecation with passage of hard, dry stool.

Consultand A designated "index" patient who seeks genetic counseling without being known to have a given genetic disorder, around which a pedigree is often constructed.

Continuity of care The process of facilitating a patient's care between and among healthcare providers and settings based on health needs and available resources.

Cooperative play A type of play that emerges in school years when children join into groups to achieve a goal or play a game.

Coping The use of learned behavioral and cognitive strategies to manage or relieve perceived stress; the cognitive and behavioral responses that help a person manage specific internal and external demands that exceed personal resources, enabling the person to solve problems and to respond appropriately.

Copy number variation An additional source of human genetic variation in which stretches of DNA of variable size are replicated one or more times.

Cor pulmonale Obstruction of pulmonary blood flow that leads to right ventricular hypertrophy and heart failure.

Crepitus A crinkly sensation palpated on the chest surface caused by air escaping into the subcutaneous tissues.

Critical thinking An individualized, creative thinking or reasoning process that nurses use to solve problems.

Crossing over A process that occurs during meiosis in which homologous maternal and paternal chromosomes break and exchange corresponding sections of DNA and then rejoin; this process can cause an exchange of alleles between chromosomes and provides human diversity.

Cryotherapy The use of cold or cold agents (liquid nitrogen) to treat specific injuries or conditions. Often used for treating warts and other skin conditions.

Cultural competence The ability to understand and effectively respond to the needs of patients and families from different cultural backgrounds.

Culture The beliefs, values, attitudes, and practices that are accepted by a population, community, or an individual.

Cushing triad Reflex response associated with increased intracranial pressure or compromised blood flow to the brainstem; characterized by hypertension, increased systolic pressure with wide pulse pressure, bradycardia, and irregular respirations.

Cyberbullying A situation in which a child or adolescent is targeted by another via Internet posting or other digital technology and threatened, tormented, harassed, humiliated, or embarrassed.

Cyclic vomiting Repeated severe vomiting of an episodic nature.

Cytogenetics The study of chromosomes and alterations to health caused by abnormalities in the number or structure of chromosomes.

D

Deamination Removal of an amino group from an amino compound.

Death anxiety A feeling of apprehension or fear of death.

Death imagery Any reference to death or death-related topics, such as going away, separation, funerals, and dying, given in response to a picture or story that would not usually stimulate other children to discuss death-related topics.

Debridement Enzyme action to clean a lesion and dissolve fibrin clots or scabs; or removal of dead tissue to speed the healing process.

Decibels Units used to measure the loudness of sounds.

Deciduous teeth Primary set of 20 teeth that is complete by about 2 years of age and will be lost during childhood, beginning at about 6 years.

Decontamination The removal of chemicals and nerve agents from the skin.

Deep sedation A controlled state of depressed consciousness or unconsciousness in which the child may experience partial or complete loss of protective airway reflexes.

Defense mechanisms Techniques used by the ego to unconsciously change reality, thereby protecting itself from excessive anxiety.

Dehydration The state of body water deficit.

Dermatophytoses Fungal infections that affect primarily the skin, but also may affect the hair and nails.

Desaturated blood Blood with a lower than normal oxygen level resulting when a heart defect causes oxygenated and unoxygenated blood to mix.

Development The process of increasing capability or function.

Developmental delay A delay in mastering functions, such as motor coordination and behavioral skills.

Developmental disability Any of a variety of chronic conditions that are characterized by mental or physical impairments. Intellectual disability, pervasive developmental disorder, cerebral palsy, and sensory loss are examples of developmental disabilities.

Developmental surveillance A flexible, continuous process of skilled observations that provides data about the child's capabilities, allows for early identification of any neurologic problems, and helps to verify that the home environment is stimulating.

Dialysate The solution used in dialysis.

Diarrhea Frequent passage of abnormally watery stool.

Dietary Reference Intakes (DRIs) A set of nutrient values established by the Food and Nutrition Board of the Institute of Medicine (IOM) and the National Academy of Science that can be used to assess and plan intake for individuals of different ages.

Diffusion Movement of molecules across a membrane from an area of higher concentration to lower concentration.

Direct transmission The passage of an infectious disease through physical contact between the source of the pathogen and a new host.

Disability A limitation that interferes with a child's ability to fully participate in society, which can be related to medical impairment (chronic health condition), functional limitation (mobility, self-care, communication, or learning behavior impairment), or a mental condition that interferes with social interactions.

Disaster A serious and massive event that impacts many people and causes extensive damage, hardship, death, injuries, and psychologic trauma.

Disaster preparedness Community planning for responses to natural and man-made disasters that involve multiple casualties.

Discipline A method for teaching the rules that govern behavior or conduct.

Disequilibrium syndrome Rapid changes in the body's water and electrolyte balance during treatment.

Dislocation Displacement of a bone from its normal articulation with a joint.

Distraction The ability to focus attention on something other than pain, such as an activity, music, or a story.

Dominant A characteristic or gene that is apparent even when the relevant gene is present in only one copy; a person with a dominant gene usually expresses that gene trait.

Dramatic play A type of play in which a child acts out the drama of daily life or in which medical situations encountered are reenacted by the child.

Dwarfism A genetic condition usually resulting in an adult height of 58 inches or less. The most common cause of dwarfism is achondroplasia, which causes short arms and legs. The torso and head are approximately normal size, but decreased growth of long bones causes short stature.

Dysmenorrhea Menstrual pain or cramping.

Dysmorphology The study of human congenital defects or abnormalities of body structure that begin before birth.

Dysphagia Difficulty in swallowing.

Dysphonia Muffled, hoarse, or absent voice sounds.

Dysplasia Abnormal development resulting in altered size, shape, and cell organization.

Dyspnea Shortness of breath; difficulty breathing.

E

Early childhood caries (ECC) The presence of one or more decayed, missing, or filled tooth surfaces in primary teeth in a child 71 months of age or younger; frequently caused by drinking from a bottle or nursing for prolonged periods, especially when sleeping; previously referred to as *nursing bottle mouth syndrome* and *baby bottle tooth decay*.

Early intervention Special services provided by state or local education programs for infants and toddlers up to age 3 years who have a developmental delay or are at risk for developmental delay in the hopes that these children will have a lowered total cost of educational services.

Ecchymosis Bruising.

Echolalia A compulsive parroting or repetition of what is heard.

Ecologic theory A theory of development that emphasizes the importance of interactions between the developing child and the settings in which the child lives.

Ecomap An illustration of a family's relationships and social networks.

Edema An accumulation of excess fluid in the interstitial spaces.

Electroanalgesia A method of delivering electrical stimulation to the skin by electrodes, to compete with pain stimuli for transmission to the spinal cord; also known as *transcutaneous electrical nerve stimulation (TENS).*

Electrolytes Charged particles (ions) dissolved in body fluid.

Emancipated minors Economically self-supporting adolescents under 18 years of age not subject to parental control (e.g., married, pregnant, enlisted, or incarcerated).

Emergency preparedness Readiness to manage a healthcare emergency that involves planning, equipment and supplies for responses, and provider training and guidelines for action when an emergency occurs.

Emollient A topical product that soothes and softens the skin.

Emotional abuse Shaming, ridiculing, embarrassing, or insulting a child.

Emotional neglect A caretaker's inability to meet the psychosocial needs of a child.

Encephalopathy Cerebral dysfunction resulting from an insult (e.g., toxin, injury, inflammation, or anoxic event) of limited duration; the tissue damage is often permanent, but the dysfunction may improve over time.

Endogenous pyrogens Pyrogens (chemicals, interleukins, interferons, and tumor necrosis factor) released in response to an invasive organism that travel through the circulatory system to the hypothalamus, where they trigger the production and release of prostaglandins, resulting in the fever response.

Endorphins Opioidlike substances produced by the body.

End-stage renal disease (ESRD) Irreversible kidney failure.

Enteral therapy Nutrition introduced through the intestinal tract, including oral or tube feedings.

Enuresis Repeated involuntary voiding by a child who has reached the age at which bladder control is expected.

Epicanthal fold An extra fold of skin covering all or part of the lacrimal caruncle of the medial canthus (nasal side) of the eye.

Epidemiologist A specialist with training in the study of patterns of diseases or health risks in a population.

Epigenetic Describes any factor that can affect gene function (usually by changing gene expression, or translation) without changing the DNA sequence.

Equianalgesic dose The amount of a drug, when administered orally, that produces the same level of analgesia as when it is administered parenterally.

Equinus A condition that limits dorsiflexion to less than normal; usually associated with clubfoot.

Ergogenic aids Products that enhance physical performance.

Erythropoiesis Formation of red blood cells.

Eschar Slough or layer of dead skin or tissue; the tough leathery scab that forms over severely burned areas.

Escharotomy Incision into constricting dead tissue of a burn injury to restore peripheral circulation.

Esotropia Momentary inward deviation of the eyes.

Ethics The philosophic study of morality, and the analysis of moral problems and moral judgments.

Ethnicity A social identity that is associated with shared beliefs, behaviors, patterns, and cultural heritage.

Euthyroid Normal thyroid state; thyroid hormones in appropriate balance.

Evidence-based practice An approach to problem solving and decision making that is based on the consideration of data from research, statistical analysis, quality measures, risk management measurements, and other sources of reliable information.

Exophthalmos Prominent or bulging eyes.

Exotropia Outward deviation of the eyes ("wall-eyes").

Expressive jargon Use of unintelligible words with normal speech intonations as if truly communicating in words; common in toddlerhood.

Extracellular fluid The fluid in the body that is outside the cells.

Extravasation Damage that occurs when a chemotherapeutic drug leaks into the soft tissue surrounding the infusion site.

F

Faith-based belief An organized system of shared beliefs regarding the significance of the nature, cause, and purpose of life and the universe.

Family Refers to two or more persons who are joined together by marriage, birth, or adoption and live together in the same household.

Family-centered care The effort to address and meet the emotional, social, and developmental needs of children and families seeking health care in all settings.

Family crisis An event that causes problems for a family that for a time seem insurmountable and with which the family is unable to cope in its usual ways.

Family strengths Relationships, processes, and resources that families can use during times of adversity and change to manage stressors.

Fever An increased body temperature of 38.0°C (100.4°F) or higher taken by rectal or tympanic route, and 37.8°C (100°F) or higher by the oral or temporal route.

Filtration Movement of fluid into or out of capillaries as the net result of several opposing forces.

Focal Specific area of the brain; often used to describe seizures or neurologic deficits.

Food allergy An IgE-mediated reaction to a given food that is potentially systemic, characteristically rapid in onset, and may be manifested as swelling of the lips, mouth, uvula or glottis, generalized urticaria, and, in severe reactions, anaphylaxis.

Food insecurity An inability or uncertainty that one will be able to acquire or consume adequate quality or quantity of foods in socially acceptable ways.

Food intolerance An abnormal physiologic response (flatulence, sweating, hives, indigestion) to a food that is not immunoglobulin E (IgE)–mediated.

Food jags Eating only a few foods for several days or weeks.

Food security Access at all times to enough nourishment for an active, healthy life.

Foster care The provision of protection and shelter for a child in an approved living situation away from the family of origin.

Futility A situation in which treatments do not provide a clear clinical benefit.

G

Gamete Female or male germ cell; contains a haploid number of chromosomes.

Gay An adjective used to describe or refer to a homosexual male.

Gene A sequence of DNA on a chromosome that represents a fundamental unit of heredity; occupies a specific spot on a chromosome (gene locus).

Gene expression When the protein product of a gene is visible (presence of a body structure or identifiable through biochemical tests such as insulin or phenylalanine levels).

Genetic disease Any disease associated with gene dysfunction. Genetic diseases have traditionally been thought of as relatively rare inherited diseases, but it is now known that nearly all diseases have a genetic component.

Genogram A pedigree that displays information about a family's health history over at least three generations.

Genome The entire DNA sequence that makes up the complete genetic information of a gamete, an individual, a population, or a species.

Genomewide association study A rapid examination of many common genetic variations in DNA or genomes, in different individuals, to identify genetic variations associated with a certain disease.

Genomics The study of all the genes in the human genome together, including their interactions with each other, the environment, and the influence of other psychosocial and cultural factors.

Genotype The genetic composition of an individual.

Glucagon A hormone produced by the pancreas that helps release stored glucose from the liver.

Gluconeogenesis Formation of glycogen from noncarbohydrate sources such as protein or fat.

Glycosuria Abnormal amount of glucose in the urine.

Goiter Enlargement of the thyroid gland.

Graft-versus-host disease A series of immunologic responses mounted by the host of a transplanted organ with the purpose of destroying the transplant cells.

Growth An increase in physical size.

H

Hazing An activity that is forced on an individual that causes humiliation and is required for membership in an organization or group. It can sometimes be harmful.

Health A state of complete physical, mental, and social well-being and not merely the absence of disease and infirmity.

Health maintenance Activities that preserve an individual's present state of health and prevent disease or injury occurrence.

Health promotion Activities that increase well-being, enhance wellness or health, and lead to actualization of positive health potential; strategies that seek to foster conditions to allow populations to be healthy and to make healthy choices.

Health supervision The process of health promotion services, growth and development monitoring, and disease and injury prevention at key intervals throughout the child's life.

Heaving Lifting of the chest wall during contraction.

Hemarthrosis Bleeding into joint spaces.

Hematopoiesis Blood cell production.

Hemodynamics Passage of blood through the heart and pulmonary system and pressures generated by the blood.

Hemoglobinopathy Disease characterized by abnormal hemoglobin.

Hemoptysis Coughing up blood from the respiratory tract.

Hemosiderosis Increased storage of iron in body tissues; associated with diseases involving the destruction of red blood cells.

Herd immunity The protection provided by a large group of persons who have immunity to a disease and indirectly protect others without immunity by reducing the risk for exposure and infection.

Hernia The protrusion or projection of a body part or structure through the muscle wall of the cavity that normally contains it.

Herniation Protrusion of brain contents through the cranial vault at the base of the skull into the brainstem area.

Heterozygous Nonidentical copies of a particular gene (different alleles) on the paired chromosomes.

Homologous chromosomes Chromosomes that are members of the same pair and normally have the same number and arrangement of genes; usually one copy is from the mother and the other copy is from the father.

Homosexuality Sexual attraction to people of the same sex.

Homozygous A genotypic situation in which two similar genes occur at a given locus on homologous chromosomes.

Hospice A philosophy of care that focuses on helping persons with short life expectancies to live their remaining lives to the fullest—without pain and with choices and dignity.

Human genome The entire DNA sequence of an individual.

Hydronephrosis Accumulation of urine in the renal pelvis as a result of obstructed outflow.

Hyperbilirubinemia An abnormally elevated serum bilirubin level.

Hypercapnia Greater than normal amounts of carbon dioxide in the blood.

Hypersensitivity response An overreaction of the immune system, responsible for allergic reactions.

Hypersplenism A syndrome characterized by splenomegaly and blood cell deficiencies.

Hypertelorism Widely spaced eyes.

Hypertonic dehydration (or hypernatremic dehydration) Fluid loss characterized by a proportionately greater loss of water than sodium.

Hypertonic saline Fluid more concentrated with salt than body fluid.

Hypoplastic Small and nonfunctional.

Hypotonic dehydration (or hyponatremic dehydration) Fluid loss characterized by a proportionately greater loss of sodium than water.

Hypotonic fluid Fluid that is more dilute (contains less salt) than normal body fluid.

Hypoxemia Lower than normal amounts of oxygen in the blood.

Hypoxia Lower than normal amounts of oxygen in the tissues.

I

Immunodeficiency A state of the immune system in which it cannot cope effectively with foreign antigens; a state of decreased responsiveness of the immune system.

Immunoglobulin A protein that functions as an antibody. Immunoglobulins are responsible for humoral immunity.

Inborn errors of metabolism Hereditary deficiencies of a specific enzyme needed for normal metabolism of specific chemicals.

Incarceration Occurs when the presence of intestine in the groin causes constriction of the blood supply to the scrotal sac, leading to intestinal strangulation and testicular ischemia.

Incest Sexual activity between family members close enough that marriage between them would be legally or culturally prohibited.

Incidental findings Unanticipated, abnormal results of genetic testing that are not relevant to the diagnostic indication for which the test was ordered.

Incubation period The time interval between exposure to an infectious disease and development of symptoms.

Independent assortment The random distribution of different combinations of parental genes to gametes.

Indirect transmission The passage of an infectious disease (to a person by contact with contaminated objects or by vectors) involving survival of pathogens outside humans before they invade a new host.

Individualized approach An assessment approach that involves measuring individual children seen in a clinic, sharing results with the family, and addressing appropriate teaching about weight control and nutritious intake.

Individualized education plan (IEP) A form of education planning/intervention that is developed for a child with cognitive, motor, social, and communication impairments who needs special education services. The IEP is jointly planned with the school administrator, teacher, parents, and other special support professionals as appropriate for the child's condition.

Individualized family service plan (IFSP) A form of education planning/intervention that is developed for early intervention with infants with special healthcare needs and their families. The IFSP contains information about the services required to support a child's development and enhance the family's capacity to facilitate the child's development. The family and education service providers work as a team to plan, implement, and evaluate services specific to the family's unique concerns, priorities, and resources.

Individualized health plan (IHP) A formal mechanism to ensure that the child's health needs are managed in the school setting.

Individualized transition plan (ITP) A plan that focuses on assisting the adolescent with special healthcare needs in moving successfully from school into the community.

Induration An area of extra firmness on the skin with a distinct border.

Infant mortality Death in infants less than 12 months of age.

Infectious disease Any communicable disease caused by microorganisms transmitted from one person to another or from an animal to a person.

Informed consent A legal concept that protects a person's rights to autonomy and self-determination by specifying that no action may be taken without that person's prior understanding and freely given consent; a formal authorization by the child's parent or guardian allowing an invasive procedure to be performed or for participation in research.

Inguinal hernia A painless inguinal or scrotal swelling of variable size that occurs when abdominal tissue, such as bowel, extends into the inguinal canal.

Insensible fluid loss Fluid loss not directly measurable or observable, such as through skin and the respiratory tract.

Inspection The technique of purposeful observation by carefully looking at the characteristics of the child's physical features and behaviors. Physical feature characteristics include size, shape, color, movement, position, and location.

Insulin deficiency A condition in which the pancreas does not produce sufficient insulin (as in type 1 diabetes).

Insulin resistance An alteration of the insulin receptor that signals the presence of insulin in the interior of cells.

Intellectual disability Significant limitation in intellectual functioning and adaptive behavior, manifested by differences in conceptual, social, and practical adaptive skills, beginning before the age of 18 years.

Interstitial fluid That portion of the extracellular fluid that is between the cells and outside the blood and lymphatic vessels.

Intertriginous areas Areas where skin is in contact with other skin, (e.g., between fingers, and within skinfolds of the neck, axillae, or antecubital fossa).

Intracellular fluid The fluid in the body that is inside the cells.

Intracranial pressure Force exerted by brain tissue, cerebrospinal fluid, and blood within the cranium.

Intractable seizure A seizure that continues to occur even with optimal medical management.

Intrathecal A method of drug or medication delivery in which the drug is introduced into the spinal canal.

Intravascular fluid The portion of the extracellular fluid that is in the blood vessels.

Inversion A chromosomal alteration in which a gene or DNA sequence in a segment of a chromosome has been reversed.

Involution Rolling or turning inward; the process of decreasing in size; the reduction in size of the uterus following childbirth.

Isotonic dehydration (or isonatremic dehydration) Fluid loss that is not balanced by intake; the loss of water and sodium are in proportion.

Isotonic fluid Fluid that has the same osmolality as normal body fluid.

J

Joint custody A legal situation in which both parents have equal responsibility and legal rights for a child, regardless of where the child lives.

K

Karyotype A picture of an individual's chromosomes arranged in a standard order.

Keloid Overdevelopment or hypertrophy of a scar that extends beyond the wound edges and above the skin line because of excess collagen.

Kerion A large tender boggy mass on the scalp with drainage; associated with tinea capitis.

Killed virus vaccine A vaccine that contains a killed microorganism that is still capable of inducing the human body to produce antibodies to the disease.

Kinesthesia The sense of one's body position and movement.

Kussmaul respirations Increased rate and depth of respirations (hyperventilation).

L

Lacto-ovovegetarians Vegetarians who eat eggs and dairy products.

Lactovegetarians Vegetarians who eat dairy products but not eggs.

Laryngospasms Spasmodic vibrations of the larynx, which create sudden, violent, unpredictable, involuntary contraction of airway muscles.

Legal guardianship A permanent placement option for the child, often with relatives, in which parental rights are not terminated.

Lesbian An adjective used to describe or refer to a homosexual female.

Leukocytosis A higher than normal leukocyte count.

Leukopenia A lower than normal white blood cell (leukocyte) count.

Level of consciousness The most important indicator of neurologic dysfunction. Consciousness, the responsiveness to or awareness of sensory stimuli, has two components: alertness, or the ability to react to stimuli, and cognitive power, or the ability to process the data and respond either verbally or physically.

Lichenification Thickening of the skin with more visible skin furrows.

Life-threatening condition A condition in which there is a likelihood that the child will die prematurely.

Limit setting Established rules or guidelines for behavior.

Live virus vaccine A vaccine that contains the microorganism in a live but attenuated, or weakened, form.

Lymphangitis Inflammation of the lymphoid system draining the site of infection that is seen as tender, erythematous streaks extending in a proximal direction from the site of injury.

M

Macronutrients The major building blocks of the body: carbohydrates, protein, and fat.

Major anomaly A serious structural defect present at birth that may have severe medical or cosmetic consequences that interfere with normal functioning of body systems, lead to a lifelong disability, or even cause early death.

Malignant The progressive growth of a tumor that will, if not checked by treatment, spread to other sites in the body and result in death.

Mature minors Adolescents between 14 and 18 years of age who are able to understand treatment risks and who in some states can consent to or refuse treatment.

Medically fragile Having a complex chronic health condition that requires skilled nursing and often technology support for vital functions.

Meiosis The process of cell division that occurs in the maturation of sperm and ova that decreases their number of chromosomes by one half.

Menorrhagia Heavy menstrual bleeding.

Mental health Foundational to a sense of personal well-being, physical health, and psychologic stability; it involves successful engagement in activities and relationships and the ability to adapt and cope with change.

Metastasis The spread of cancer cells to other sites in the body.

Microarray analysis A laboratory method in which labeled RNA from a specimen is added to a glass slide or other platform on which DNA fragments are arranged. Useful for identifying and quantifying mRNA and indicating which genes are actively expressed in a tissue.

Microcephaly A small brain with a head circumference below the third percentile on growth curves.

Micronutrients Substances needed in small quantities for healthy body functioning; vitamins and minerals are micronutrients.

Minor anomaly An unusual morphologic feature that is of no serious medical or cosmetic concern.

Mitosis Process of cell division whereby both daughter cells have the same number and pattern of chromosomes as the original cell.

Mixed hearing loss Hearing loss having a combination of conductive and sensorineural causes.

Modeling Imitating the behavior of someone else.

Moderate sedation A lower dose of a sedative that enables the child to maintain protective reflexes independently, continuously maintain a patent airway, and respond to tactile and verbal stimuli.

Monosomic (monosomy) Genetic condition that occurs when a normal gamete unites with a gamete that is missing a chromosome.

Moral dilemma A conflict involving individual beliefs, social values, and ethical principles.

Morbidity An illness or injury that limits activity, requires medical attention or hospitalization, or results in a chronic condition; incidence and prevalence of certain diseases.

Mosaicism Condition of an individual who has at least two cell lines with differing karyotypes.

Multifactorial Health conditions determined by multiple factors, including genetic and environmental factors, each having an additive effect.

Myelodysplasia Any malformation of the spinal cord and spinal canal.

Myelosuppression A decreased production of blood cells in the bone marrow.

Myringotomy A procedure whereby an incision is made in the tympanic membrane to drain fluid.

N

Nadir The lowest point, such as for a laboratory value or serum blood titer.

Nasal flaring A sign of respiratory distress; an effort the child makes to widen the airway by widening the nares with breathing.

Natural immunity The body's defenses present at birth, such as intact skin, body pH, natural antibodies from the mother, and inflammatory and phagocytic properties.

Nature The genetic or hereditary capability of an individual.

Neoplasms Cancerous growths.

Nephrotic syndrome An alteration in kidney function secondary to increased glomerular basement membrane permeability to plasma protein.

Neural tube Cell tissue that ultimately develops into the central nervous system, including the brain and spinal cord.

Neural tube defect Malformation of embryonic tissue that develops into the central nervous system and includes anencephaly, encephalocele, spina bifida, and myelodysplasia.

Neurogenic bladder The result of urinary tract obstruction related to an interrupted nerve supply to the bladder.

Neuropathic pain A form of chronic pain, initiated or caused by a primary lesion or dysfunction of the nervous system; an abnormal processing of pain stimuli by the peripheral or central nervous system.

Neutropenia A low neutrophil count.

Nightmares Frightening dreams that awaken the child, who is often crying and upset.

Night terrors (or sleep terrors) A situation in which the child cries out, appears frightened, and has tachycardia and tachypnea while sleeping, but in contrast to nightmares, the child having a night terror is not fully awake and may appear disoriented.

Nociceptive pain The perception of pain; the normal processing of pain stimuli caused by tissue injury or damage.

Nociceptors Free nerve endings at the site of tissue damage that are able to detect and respond to chemical, mechanical, and thermal stimuli.

Nondisjunction An error in cell division in which a pair of homologous chromosomes does not separate as expected, resulting in monosomy or trisomy in gametes.

Nonsteroidal anti-inflammatory drugs (NSAIDs) Drugs that are effective for the relief of mild to moderate pain and chronic pain.

Nosocomial infection An infection acquired in a healthcare agency, not present at the time of entrance to the agency.

Nuchal rigidity Resistance to neck flexion.

Nurture The effects of environment on an individual's performance.

Nutrition Taking in of food and assimilating it metabolically for use by the body.

O

Object permanence The knowledge that an object or person continues to exist when not seen, heard, or felt.

Occult blood Blood that is present in small quantities and is measurable only by laboratory testing.

Oliguria Diminished urine output (less than 0.5 to 1 mL/kg/hr).

Oncogene A portion of the DNA that is altered and, when duplicated, causes uncontrolled cellular division.

Oncotic pressure The part of the blood osmotic pressure that results from plasma proteins; also called blood colloid osmotic pressure.

Opioids Analgesics commonly given for severe pain, such as after surgery or a severe injury.

Opisthotonic position Rigid hyperextension of the head and neck.

Opisthotonos Rigid hyperextension of the entire body.

Opportunistic infection An infection that is often caused by normally nonpathogenic organisms in persons who lack normal immunity.

Orchitis Inflammation of the epididymis, pain on testicular palpation, and scrotal swelling, often associated with mumps infection in postpubertal males.

Organelle A small cellular structure such as a ribosome or mitochondria that performs specific cellular functions.

Osmolality The amount of concentration of a fluid; technically, the number of moles of particles per kilogram of water in the solution.

Osmosis Movement of water across a semipermeable membrane into an area of higher particle concentration.

Ossification Formation of bone from fibrous tissue or cartilage.

Osteodystrophy A complex bone disease process of chronic kidney disease in which there is increased resorption of bone caused by chronic hyperparathyroidism.

Osteotomy Surgical cutting of bone.

Ostomy An artificial abdominal opening into the urinary or gastrointestinal canal that provides an outlet for the diversion of urine or fecal matter.

Outcome expectancy What a person expects to get from performing a certain behavior.

P

Pain An unpleasant sensory and emotional experience associated with actual or potential tissue damage. Pain exists when the patient says it does.

Palliative care A multidisciplinary care approach for children with life-shortening disorders and their families. It is intended to relieve suffering of all types (physical, psychologic, spiritual, and social); to enhance quality of life for patients and their families; to facilitate informed decision making by the patient, family, and healthcare professionals; and to improve care coordination.

Palliative procedure Intervention used to preserve life in children with a potentially fatal or lethal condition; a surgical procedure that does not create normal anatomic or hemodynamic results.

Palpation The technique of touch to identify characteristics of the skin, internal organs, and masses. Characteristics include texture, moistness, tenderness, temperature, position, shape, consistency, and mobility of masses and organs.

Pancytopenia A decreased number of blood cell components.

Pandemic flu A worldwide influenza epidemic.

Paradoxical breathing Severe respiratory distress in which the chest falls and the abdomen rises on inspiration.

Parallel play A type of play that emerges in toddlerhood when children play side by side with similar or different toys, demonstrating little or no social interaction.

Parenting A leadership role in the family in which children are guided to learn acceptable behaviors, beliefs, morals, and rituals of the family and to become socially responsible contributing members of society.

Partnership A relationship in which participants join together to ensure healthcare delivery in a way that recognizes the critical roles and contributions of each partner in promoting health, preventing illness, and managing healthcare conditions.

Passive immunity Immunity produced through introduction of specific antibodies to the disease, which are usually obtained from the blood or serum of immune persons and animals. Does not confer lasting immunity.

Patient-controlled analgesia (PCA) A method of pain control in which anesthesia, usually morphine, is initially administered by the anesthesiologist and subsequent doses are self-administered by pushing a button controlled by a special IV pump system.

Patient safety The freedom from unintentional injury caused by medical care, including such injuries that could be related to adverse drug events, misidentification of the patient, and healthcare-associated infections

Pediatric healthcare home The site of comprehensive, family-centered, continuous, culturally sensitive, coordinated, and compassionate health care by a pediatric healthcare professional focused on the overall well-being of children and families.

Pedigree Graphic representation of a family tree.

Penetrance The percentage or likelihood that an individual who has inherited a gene mutation will actually express the disease signs and symptoms in his or her lifetime.

Percussion The technique of striking the surface of the body, either directly or indirectly, to set up vibrations that reveal the density of underlying tissues and borders of internal organs.

Periodic breathing Sporadic episodes of apnea, not associated with cyanosis, that last for about 10 seconds and commonly occur in preterm infants.

Peristalsis A progressive, wavelike muscular movement that occurs involuntarily throughout the gastrointestinal tract.

Petechiae Small pinpoint red or purple spots on the mucous membranes or skin.

pH Negative logarithm of the hydrogen ion concentration; used to monitor the acidity of body fluid.

Pharmacogenomics The study of how an individual's genotype affects his or her response to medications.

Phenotype The whole physical, biochemical, and physiologic makeup of an individual as determined both genetically and environmentally.

Phimosis A structural defect in which the foreskin over the glans penis cannot be retracted.

Phototoxic A rapid nonimmunologic reaction of the skin when exposed to sunlight.

Physical abuse The deliberate maltreatment of another individual that inflicts pain or injury and may result in permanent or temporary disfigurement or even death.

Physical dependence The physiologic adaptation to an analgesic or sedative drug at the level of the peripheral and central neurons that may lead to withdrawal.

Physical neglect The deliberate withholding of or failure to provide the necessary and available resources to a child.

Physiologic anorexia A decrease in appetite manifested when the extremely high metabolic demands of infancy slow to keep pace with the more moderate growth rate of toddlerhood.

Pica An eating disorder characterized by ingestion of nonfood items or food items consumed in abnormal quantities or forms.

Pitting edema A "pit" or concave indentation that remains after an edematous area is pressed downward by the examiner's fingers.

Play therapy A therapeutic intervention often used with preschool and school-aged children. The child reveals conflicts, wishes, and fears on an unconscious level while playing with dolls, toys, clay, and other objects.

Polycythemia An abnormal increase in the number of total red blood cells in the body's circulation.

Polydipsia Excessive thirst.

Polyphagia Excessive or voracious eating.

Polypharmacy A term used to describe the act of taking multiple drugs at one time to treat multiple health conditions.

Polysomnography A sleep study that simultaneously records the sleep state, gas exchange, breathing efforts, cardiac rhythm, and muscle activity and movement.

Polyuria Passage of a large volume of urine in a given period.

Population-based approach Health assessment and intervention performed with a group of children.

Postictal period Period after seizure activity during which the level of consciousness is decreased.

Postpartum The period after giving birth.

Posturing Abnormal position assumed after injury or damage to the brain that may be seen as extreme flexion or extension of the limbs.

Practice guideline A consensus of evidence-based and expert opinion statements about the appropriate care for a child with a specific diagnosis that is used to assist healthcare providers to make decisions about the care of a child with that condition.

Prebiotic A nondigestible food ingredient that can stimulate growth or activity of probiotic bacteria.

Preload Volume of blood in the ventricle at the end of diastole that stretches the heart muscle before contraction.

Primary care The range of healthcare services that include health promotion, health maintenance, episodic acute care, and health maintenance care for children with chronic conditions.

Primary immune deficiency Congenital immunodeficiency.

Primary immune response The process in which B lymphocytes produce antibodies specific to a particular antigen on first exposure.

Proband The family member around whom a family history is collected.

Probiotic A food supplement containing a live microorganism that alters the balance of gut microflora, thereby providing a health benefit.

Prodrome The phase of early manifestations of the infection until the development of the overt clinical syndrome.

Projectile vomiting Vomiting in which the stomach contents are ejected with great force.

Prostration Extreme exhaustion.

Protective factors Characteristics of a child and family that provide strength and assistance when dealing with a crisis.

Protocol A plan of action for chemotherapy that is based on the type of cancer, its stage, and the particular cell type.

Proto-oncogene A gene that regulates cellular growth and development but can become an oncogene, capable of causing cancerous growth.

Proximodistal development The process by which development proceeds from the center of the body outward to the extremities.

Pseudohermaphroditism Ambiguous development of the external genitalia.

Pseudohypertrophy Enlargement of the muscles as a result of infiltration by fatty tissue.

Psychodrama Being assigned and playing out roles spontaneously in a therapeutic setting to assist in understanding of the dynamics of the situation.

Puberty The developmental period between childhood and attainment of adult sexual characteristics and functioning.

Punishment The action taken to enforce the rules when the child misbehaves.

Purpura Bleeding into the tissues, particularly beneath the skin and mucous membranes, causing lesions that vary from red to bluish purple.

Pyeloplasty Removal of an obstructed segment of the ureter and reimplantation into the renal pelvis.

Q

Quality improvement The continuous study of systems, services, and processes of care, and using that information to improve healthcare processes, services, and patient outcomes.

R

Race A group of people who share biologic similarities such as skin color, bone structure, and genetic traits. Examples of races include White (sometimes called Caucasian or European American), Black (sometimes called African American in the United States), Hispanic, Natives (such as Native Americans, Alaskan Native, Hawaiian Native, and First Nation people of Canada), and Asian.

Radiation A therapy that involves unstable isotopes that release varying levels of energy to cause breaks in the DNA molecule and thereby destroy cells. It is often used for the local and regional control of cancer, and in combination with surgery and chemotherapy; it may be curative or palliative.

Radioallergosorbent test (RAST) A technique in which radioimmunoassay is used to measure the presence in the blood of IgE antibodies to specific allergens.

Radio-frequency ablation The use of radio energy (heat) to destroy a very small section of the myocardium through which an accessory conduction pathway passes.

Recessive A characteristic that is apparent only when two copies of the gene encoding it are present, one from the mother and one from the father.

Recombinant forms Genetically altered organisms used in a vaccine to produce immunity with a minimum of side effects.

Red reflex The orange-red glow of the vascular retina seen as a light shines through the cornea, aqueous humor, lens, and vitreous humor to the retina.

Regression Return to an earlier behavior; a defense mechanism that may be displayed by children during times of stress.

Rehabilitation Assisting a child with physical or mental challenges to reach full potential through therapy and education that considers the physiologic, psychologic, and environmental strengths and limitations of the child.

Reliability When consistent results are obtained when measured by the same rater or other raters.

Religion An organized system of shared beliefs regarding the significance of the nature, cause, and purpose of life and of the universe.

Renal insufficiency Any degree of renal failure in which the kidneys' ability to conserve sodium and concentrate the urine decreases.

Repression Involuntary forgetting; a defense mechanism often displayed by children with life-threatening or mortal illness.

Resilience The family's capacity to develop strengths and abilities to "bounce back" from stress and challenges.

Resiliency theory An assessment theory that states that all individuals experience crises that lead to adaptation and development of inner strengths and the ability to handle future crises.

Respiratory depression An unresponsiveness and progressively decreasing respiratory rate that may progress to respiratory arrest.

Respite care Short-term home care to relieve the primary caregiver and allow time away from home.

Retractions A visible "drawing in" of the skin of the neck and chest that occurs on inspiration in infants and young children in respiratory distress; visible depression of tissue is seen between the ribs of the chest wall with each inspiration.

Risk factors Characteristics of a child and family that promote or contribute to their challenges when dealing with a crisis.

Risk management A process established by a healthcare institution to identify, evaluate, and reduce the risk of injury to patients, staff, and visitors, and thereby reduce the institution's liability.

Rooming in Practice in which parents stay in the child's hospital room during the course of the child's hospitalization.

S

Saline A mixture of salt and water; normal saline refers to the mixture of salt and water in equal concentration in body fluids.

Screening Procedures used to detect the presence of a health condition before symptoms are apparent.

Secondary cancers Cancers (most commonly solid tumors) that appear subsequent to the primary cancer and treatment but are of a different histologic type. Also called *second malignant neoplasms (SMNs)*.

Secondary immune deficiency Acquired immunodeficiency.

Secondary immune response The body's response to an antigen at any time other than the initial exposure.

Sedation A medically controlled state of depressed consciousness used for painful diagnostic and therapeutic procedures.

Self-concept Evaluation of the self in certain specific areas, such as those related to academic achievement, athletic ability, physical appearance, and social interactions.

Self-efficacy A person's belief in the ability to perform a behavior to produce a desired outcome.

Self-esteem Feelings and beliefs of competence and worth as an individual, ability to meet challenges, and ability to learn lessons from success and failure; feelings of self-worth or value.

Self-regulation Infant's ability to maintain state and self-console (e.g., by sucking the fingers to stay calm instead of crying).

Sensible fluid loss Fluid loss that is measurable and observable, such as urine and wound drainage from tubes.

Sensorineural hearing loss Hearing loss caused by damage to the inner ear structures or the auditory nerve.

Separation anxiety Distress behaviors observed in young children separated from familiar caregivers.

Sequelae A chronic condition resulting as a complication of a disorder.

Sequence A cascade of events that are initiated by a single factor and lead to birth defects or congenital abnormalities.

Sex chromosome The X or Y chromosomes, which are responsible for gender determination.

Sexuality A person's view of self as a sexual being.

Shock An acute, complex state of circulatory dysfunction resulting in failure to deliver sufficient oxygen and other nutrients to meet cell and tissue demands.

Shunt An abnormal anatomic or surgically created opening in the septum between the systemic and pulmonary circulation.

Single nucleotide polymorphism (SNP) A variation in DNA sequence in which a single nucleotide base (A, T, C, or G) is substituted for another.

Sleep hygiene Behaviors that foster a regular and sufficient sleep pattern and daytime alertness.

Solitary play When infants play by themselves.

Spinal shock A concussion of the spinal cord resulting in the transient suppression of nerve function below the level of the acute injury.

Spiritual dimension A connection with a greater power than that in the self that guides a person to strive for life purpose, joy, peace, and fulfillment.

Spiritual health The ability to develop a spiritual nature, including awareness of a life purpose or meaning, a sustaining power during times of stress, a feeling of harmony with the universe, and a sense of fulfillment.

Spirituality An individual's experience and own interpretation of a relationship with a Supreme Being.

Sprain A tearing of ligaments usually caused when a joint is twisted or otherwise traumatized.

Stakeholders All community residents, policy makers, health providers, and funders concerned with the outcome of the community assessment.

Status epilepticus A prolonged continuous seizure of 15 minutes or evidence of intermittent seizures noted from clinical signs or EEG tracings lasting more than 15 minutes without full recovery of consciousness between seizures.

Stenosis Narrowing of a valve or valve area below the valve or in the blood vessel.

Stent A device used to maintain patency of the urethral canal after surgery.

Stereotyping The assumption that all members of a cultural, ethnic, or racial group are alike and share the same characteristics.

Stereotypy Repetitive, obsessive, machine-like movements, commonly seen in autistic or schizophrenic children.

Stoma An opening, commonly in the abdominal wall, to provide for drainage from the intestinal or urinary systems.

Stranger anxiety Wariness of strange people and places, often shown by infants between 6 and 18 months of age.

Stridor An abnormal, high-pitched, crow-like respiratory sound caused when air moves through a narrowed larynx or trachea.

Stroke volume The amount of blood ejected with each ventricular contraction.

Subluxation Partial or complete dislocation of a joint.

Support systems The extended network of family, friends, and religious and community contacts that provide nurturance, emotional support, and direct assistance to parents.

Syncope Transient loss of consciousness and muscle tone.

Syndrome A collection of anomalies that occur in a consistent pattern and have a common cause.

T

Tachypnea An abnormally rapid rate of respiration.

Tactile fremitus Producing vibrations by either crying or talking that can be palpated on the chest.

Technology-assisted State of depending on a medical device that is required to sustain life (mechanical ventilators, intravenous nutrition or drugs, tracheostomy, suctioning, oxygen, or nutritional support with tube feedings).

Telangiectasia Permanent dilation of superficial capillaries and blood vessels.

Tetraplegia A loss of sensation and function of the head and neck and upper and lower extremities.

Thelarche Breast development.

Therapeutic play Planned play techniques that provide an opportunity for children to deal with their fears, concerns, and stressors of health experiences related to illness or hospitalization.

Thrill A vibration that may feel like a cat's purr while palpating the precordium. It is caused by turbulent blood flow from a defective heart valve and a heart murmur.

Thrombocytopenia A low platelet count.

Thyrotoxicosis A condition that can occur when thyroid hormone is suddenly released into the bloodstream during surgery or in cases of extreme hyperthyroidism. The child experiences fever, diaphoresis, and tachycardia, progressing to shock and, if untreated, death.

Tinnitus Ringing in the ears.

Tolerance Adaptation to an opioid dosage that results in a shorter duration of drug effectiveness over time.

Tonic Continuous muscular contraction; often used to describe seizure activity.

Total parenteral nutrition (TPN) A feeding regimen accomplished entirely by intravenous injection or other nongastrointestinal route.

Toxic appearance Lethargy, poor perfusion, hypoventilation or hyperventilation, and cyanosis.

Toxicants Harmful natural or synthetic chemicals not metabolically produced by an organism.

Toxins Harmful or poisonous chemicals produced by metabolism or an organism (e.g., ricin).

Toxoid A toxin that has been treated (by heat or chemical) to weaken its toxic effects but retain its antigenicity.

Tracheostomy The creation of a surgical opening into the trachea through the anterior neck at the cricoid cartilage when long-term airway management is needed.

Transgendered An adjective used to describe or refer to someone who chooses to dress and act like a member of the opposite sex from that assigned at birth; some transgendered persons choose to have surgery and take medications to facilitate their appearance in the chosen gender.

Translocation The joining of a part of or a whole chromosome to another separate chromosome.

Transplacental immunity Passive immunity that is transferred from mother to infant.

Treatment room In a hospital or medical center, a room designated for performing treatments such as intravenous starts, blood drawing, and lumbar punctures to promote children's sense of security that their own room is a "safe" and relatively pain-free site.

Trigger An inflammatory or noninflammatory stimulus that initiates an asthmatic episode; a substance or condition, including exercise, infectious agents, allergens, fragrances, food additives, pollutants, weather changes, emotions, and stress.

Tripod position Sitting forward with arms on knees for support and extending the neck.

Trisomic (trisomy) The presence of three homologous chromosomes rather than the usual two.

Tumor suppressor genes Genetic material that controls the growth of cells, decreasing the effects of oncogenes.

Tympanogram A graph showing the ability of the middle ear to transmit sound energy; measured by inserting an airtight probe into the external ear entrance and emitting a tone.

Tympanostomy tubes Pressure-equalizing tubes inserted to drain fluid from the middle ear.

U

Uremia Toxicity resulting from the buildup of urea and nitrogenous waste in the blood.

Urethritis An infection of the urethra.

Uveitis Inflammation of the middle layer of the eye.

V

Vacuum-assisted wound closure Negative pressure wound therapy in a pump generates a vacuum or suction to remove waste materials from the wound area.

Validity When a scale or tool accurately measures the concept it was designed to measure.

Varus A condition in which the hindfoot turns inward; usually associated with clubfoot.

Vaso-occlusion Blockage of a blood vessel.

Vegan Strict vegetarian who eats no animal products.

Vegetarian One who eats no poultry, meat, or fish.

Vertical transmission The passage of disease from the mother to the fetus during the period of pregnancy.

Vesicoureteral reflux The backflow of urine from the bladder into the ureters during voiding.

Violence Threatened or actual use of physical force or power that leads to potential or actual physical or emotional trauma.

Virilization The production of masculine secondary sexual characteristics in females.

Vision A complex process of acquiring meaning from what is seen, involving the eye, brain, and related neurologic and physiologic structures.

Visual acuity Measurement of the ability to discriminate a letter or other object to test sight.

Vocal resonance How well voice sounds are transmitted over the chest.

W

Water intoxication An abnormal proportion of water to sodium in the extracellular fluid.

Wheezing A noise resulting from the passage of air through mucus or fluids in a narrowed lower airway.

Wild type gene The most common type of gene; designated as normal.

Windshield survey A walking or driving tour around a neighborhood or community for the purpose of identifying resources and characteristics of the community.

Withdrawal The physical signs and symptoms that occur when a sedative or pain drug is suddenly stopped in a patient who is physically dependent.

X

Xerosis Generally dry skin that is likely to crack and fissure.

X-linked Any gene found on the X chromosome, or traits determined by such genes; also refers to the specific mode of inheritance of such genes; one altered gene on an X chromosome in a male can produce disease, such as hemophilia.

Z

Zygote A fertilized egg.

prevent disease transmission, 362
congenital adrenal hyperplasia, 874–875
community-based nursing care, 875
congestive heart failure, 545, 547
administer and monitor prescribed medications, 545
discharge planning and home care, 547
foster development, 545
maintain oxygentaion and myocardial function, 545

promote rest, 545
provide adequate nutrition, 545
provide emotional support, 547
croup syndromes, 487–488
administer medications, 487
discharge planning and home care teaching, 487–488
maintain airway patency, 487
meet fluid and nutritional needs, 487
provide home support, 487
cystic fibrosis, 510–512
administer medications and meet nutrional needs, 511
community-based nursing care, 511–512
discharge planning and home care teaching, 511
provide psychosocial support, 511
provide respiratory therapy, 511, 511*f*
depression, 805, 806
community-based nursing care, 805, 806
discharge planning and home care teaching, 805
developmental dysplasia of the hip, 832–833
community-based nursing care, 833
discharge planning and home care teaching, 833
prevent complications resulting from immobility, 832, 833
promote normal growth and development, 833
provide cast care and correct harness alignment, 832
dying child, 273–275
autopsy, 275
communicating with child about impending death, 273, 273*t*
family support, 273, 274
physiologic care, 273
postmortem care and family support, 275
spiritual traditions regarding dying/after-death rites, 274*t*
tissue/organ donation, 275
extracellular fluid volume deficit, 412–415
discharge planning and home care teaching, 415
monitor intravenous fluid administration, 415
prevent dehydration, 412
provide oral rehydration fluids, 414, 414*t*
teach parents oral rehydration methods, 414–415
foreign-body aspiration, 480
discharge planning and home care teaching, 480
fracture, 854, 856
maintain proper alignment, 854
monitor neurovascular status, 854, 856
gastroenteritis, 685–686
discharge planning and home care teaching, 685
ensure adequate nutrition, 685
promote rest and comfort, 685
provide emotional support, 685
health promotion and maintenance, 151
encourage health promotion activities, 152
perform health supervision interventions, 152
provide anticipatory guidance, 152
health promotion and maintenance for adolescent, 203, 204
health promotion and maintenance for newborn, 164
health promotion and maintenance for school-age child, 194
health promotion and maintenance for toddler and preschooler, 178–179
hearing impairment, 463–465
facilitate ability to receive spoken information, 463, 464
facilitate ability to send information, 464–465, 465*f*
help parents meet child's education needs, 465
provide emotional support, 465
hemophilia, 603–604
discharge planning and home care teaching, 603–604
limit joint involvement and manage pain, 603
prevent and control bleeding, 603
provide emotional support, 603
hepatitis, 694
administer medications, 694
maintain adequate nutrition, 694
prevent spread of infection, 694
promote rest and comfort, 694
provide diversional activities, 694
HIV infection, 573–577
hydrocephalus, 765
community-based nursing care, 765
discharge planning and home care teaching, 765
hospital-based nursing care, 765
hyperbilirubinemia, 691
discharge planning and home care teaching, 691
hypercalcemia, 428
hyperkalemia, 424
administer intravenous solutions, 424
discharge planning and home care teaching, 424
ensure safety, 424
monitor cardiopulmonary status, 424
preventing, 424
promote adequate nutritional intake, 424
hyperthyroidism, 871–872
hypocalcemia, 429–430
hypokalemia, 426
discharge planning and home care teaching, 426
ensure adequate potassium intake, 426
ensure safety, 426
monitor cardiopulmonary status, 426
promote normal bowel function, 426
provide dietary counseling, 426
hyponatremia, 423
hypothyroidism, 870
hypovolemic shock, 558–559
immunizations, 345–348
administer vaccines, 347, 347*f*
obtain consent, 345, 347
prepare for emergencies, 348
protect vaccine potency, 345
reduce pain and anxiety, 347–348
intellectual disability, 817–818
community-based nursing care, 817–818
maintain safe environment, 817
provide assistance with adaptive functioning, 817
provide emotional support and information, 817
juvenile idiopathic arthritis, 582
community-based nursing care, 582
promote adequate nutrition, 582
promote improved mobility, 582
Legg-Calvé-Perthes disease, 835
community-based nursing care, 835
promote normal growth and development, 835
leukemia, 647–648
metabolic acidosis, 436–437
nephrotic syndrome, 714–715
administer medications, 714–715
discharge planning and home care teaching, 715
meet nutritional and fluid needs, 715
prevent infection, 715
prevent skin breakdown, 715
promote rest, 715
provide emotional support, 715

Planning and implementation (*continued*)
neuroblastoma, 641
osteomyelitis, 843, 844
osteoporosis or osteopenia, 843
otistis media, 458, 459–460
poisoning, 398
prevent recurrence, 398
provide emotional support, 398
pyloric stenosis, 667–668
discharge planning and home care teaching, 668
meet fluid and electrolyte needs, 667
minimize weight loss, 667
prevent infection, 667
promote rest and comfort, 667
provide supportive care, 668
respiratory acidosis, 434–435
community-based nursing care, 434
hospital-based nursing care, 435
respiratory alkalosis, 435
community-based nursing care, 435
ensure safety, 435
maintain pain control, 435
promote respiratory function, 435
regulate fluid status, 435
teach stress management techniques, 435
retinopathy of prematurity, 450
scoliosis, 840
discharge planning and home care teaching, 840
promote acceptance of the treatment plan, 840
seizure disorder, 752–754
administer medications, 752
community-based nursing care, 753–754
discharge planning and home care teaching, 753
ensure safety, 752
maintain airway patency, 752
provide emotional support, 752
severe combined immunodeficiency disease, 568–569
manage medication therapy, 568
prevent systemic infection, 568
promote nutritional balance, 568
promote skin integrity, 568
provide emotional support and referrals, 568–569
sexually transmitted infections, 734–735
community-based nursing care, 734–735
sickle cell disease, 597–600
control pain, 597
discharge planning and home care, 600
ensure adequate nutrition, 600
increase tissue perfusion, 597
prevent complications of crisis, 600
prevent infection, 597
promote hydration, 597
provide emotional support, 600
slipped capital femoral epiphysis, 837
systemic lupus erythematosus, 580
avoid triggers for disease flares, 580
maintain fluid balance, 580
manage side effects of medications, 580
prevent infection, 580
promote adequate nutrition, 580
promote rest and control, 580
promote skin integrity, 580
provide emotional support, 580
tobacco use, 375
tonsillitis and adenoiditis, 470, 471
discharge planning and home care teaching, 470, 471
traumatic brain injury, 780–781
community-based nursing care, 781
discharge planning and home care teaching, 781
hospital-based nursing care, 780–781
type 1 diabetes, 880, 884–886
community-based nursing care, 884–886
discharge planning and home care teaching, 884
provide education, 880, 884
provide emotional support, 884
type 2 diabetes, 890–891
community-based nursing care, 890–891
urinary tract infection, 706
discharge planning and home care teaching, 706
violence, 386–388
community-based nursing care, 386, 388
evaluation, 388
providing information, 386
visual impairment, 453–455
community-based nursing care, 454
encourage use of all senses, 453, 453*f*
promote socialization, 454
provide emotional support, 455
Planning and implementation, in nursing management
family-centered care and cultural considerations, 41, 42
genetic disorders, 62–63

Ways to Decrease the Incidence of Cancer in Children p. 615
When to Contact the Healthcare Provider p. 161

FOCUS ON

Cellular Growth p. 611
Eyes, Ears, Nose, and Throat p. 441
Fluid, Electrolyte, and Acid–Base Balance p. 405
Mental Health and Cognition p. 791
The Cardiovascular System p. 519
The Endocrine System p. 862
The Gastrointestinal System p. 656
The Genitourinary System p. 702
The Hematologic System p. 590
The Immune System p. 564
The Integumentary System p. 901
The Musculoskeletal System p. 822
The Neurologic System p. 740
The Respiratory System p. 475

GROWTH AND DEVELOPMENT

Abdominal Assessment p. 128
Auscultating Breath Sounds p. 122
Childcare Outcomes p. 213
Consent Considerations p. 12
Developmental Considerations for the Child With a Chronic Condition p. 251
Distraction Activities p. 326
Indicators of Hearing Loss p. 113
Leg Alignment p. 134
Respiratory Rate p. 122

HEALTH PROMOTION

The Adolescent With Congenital Heart Disease p. 539
The Child Receiving Cancer Treatment p. 637
The Child With a Hearing Impairment p. 464
The Child With Atopic Dermatitis p. 916
The Child With Bronchopulmonary Dysplasia p. 496
The Child With Chronic Renal Failure p. 725
The Child With Cleft Lip or Cleft Palate p. 664
The Child With Diabetes Mellitus p. 887
The Child With Hematopoietic Stem Cell Transplantation (HSCT) p. 606
The Child With Muscular Dystrophy p. 850
The Child With Myelodysplasia p. 769

MEDICATIONS USED TO TREAT

Medications Used During Cancer Treatment: Colony-Stimulating Factors p. 621
Medications Used for Cancer Chemotherapy p. 619
Medications Used for Infective Endocarditis: Prophylaxis for Dental and Invasive Respiratory Procedures p. 551

Medications Used to Treat: Acne p. 918
Medications Used to Treat: Asthma p. 499
Medications Used to Treat: Chronic Renal Failure p. 723
Medications Used to Treat: Congestive Heart Failure p. 544
Medications Used to Treat: Cystic Fibrosis p. 509
Medications Used to Treat: Gastroesophageal Reflux Disease p. 669
Medications Used to Treat: Head Lice p. 922
Medications Used to Treat: Human Immunodeficiency Virus in Children p. 572
Medications Used to Treat: Pain p. 319
Medications Used to Treat: Seizures p. 750

NURSING CARE PLAN

Home Care of the Child With Cancer p. 630
Hospital Care of the Child With Cancer p. 629
The Adolescent With Acne p. 919
The Child and Violent Behavior p. 387
The Child Coping With a Life-Threatening Illness or Injury p. 262
The Child Hospitalized With Congestive Heart Failure p. 546
The Child Hospitalized With Gastroenteritis p. 684
The Child Hospitalized With Newly Diagnosed Type 1 Diabetes Mellitus p. 881
The Child Needing Immunizations p. 346
The Child or Adolescent Hospitalized With Depression p. 805
The Child Receiving Home Peritoneal Dialysis p. 728
The Child Undergoing Surgery p. 235
The Child Undergoing Surgery for Scoliosis p. 839
The Child Who Is Overweight p. 294
The Child With Acquired Immunodeficiency Syndrome p. 574
The Child With a Chronic Condition p. 250
The Child With a Major Burn Injury p. 930
The Child With a Visual Impairment Secondary to Retinopathy of Prematurity p. 451
The Child With Bacterial Meningitis p. 757
The Child With Bronchiolitis p. 490
The Child With Cerebral Palsy p. 775
The Child With Congestive Heart Failure Being Cared for at Home p. 548
The Child With Mild or Moderate Dehydration p. 413
The Child With Otitis Media p. 459
The Child With Postoperative Pain p. 323
The Child With Previously Diagnosed Type 1 Diabetes Being Cared for at Home p. 883
The Child With Severe Dehydration p. 413
The Child With Sickle Cell Disease p. 598
The Infant With a Cleft Lip or Palate p. 660

PATHOPHYSIOLOGY ILLUSTRATED

Acute Postinfectious Glomerulonephritis p. 716
Acute Renal Failure p. 720
Airway Changes With Croup p. 485
Airway Diameter p. 477
Aldosterone Effects p. 417
Appendicitis p. 677
Asthma p. 497
Barrel Chest p. 494
Brain Injury p. 778
Brain Tumors p. 636
Buffer Responses to Excess Acid or Base p. 405
Calcium Imbalances p. 427
Capillary Dynamics and Edema p. 418
Central Nervous System Infection p. 755
Chemotherapeutic Drug Action p. 618
Classification and Types of Fractures p. 852
Classification of Burns by Depth p. 927
Clubfoot p. 828
Common Primary Skin Lesions and Associated Conditions p. 108
Conditions That Influence Nutritional Needs p. 306
Effects of Immobility p. 842
Esophageal Atresia and Tracheoesophageal Fistula p. 664
Fever p. 362
Hodgkin Disease p. 648
Human Immunodeficiency Virus p. 570
Hydrocephalus p. 763
Hypovolemic Shock p. 557
Infective Endocarditis p. 550
Mechanism of Diabetes Mellitus p. 877
Nephrotic Syndrome p. 713
Obstruction Sites in the Urinary System p. 709
Obstructive Shock due to Mediastinal Shift p. 559
Pain Perception p. 311
Phases of Wound Healing p. 904
Pneumothorax p. 514
Potassium Ions p. 423
Primary Immune Response p. 564
Proto-Oncogene Alteration p. 614
Pyloric Stenosis p. 667
Retraction Sites p. 477
Sickle Cell Disease p. 594
Slipped Epiphysis p. 836
The Bicarbonate Buffer System p. 406
The Chain of Infection Transmission p. 334
The Kidneys and Metabolic Acids p. 407
Tonsil Size With Infection p. 119
Viral Hepatitis p. 693
Visual Abnormalities p. 449

PROFESSIONALISM IN PRACTICE

Accommodations for Children With JIA p. 582
Adolescent Healthcare International Guidelines p. 195
Asthma Management by School Nurses p. 505
Clinical Guidelines p. 458
Concussion Management in the School Setting p. 782
Diagnostic and Statistical Manual of Mental Disorders (DSM) p. 793
DNAR Order in the School Setting p. 271
ELSI p. 57
Foster Care p. 79
Guidelines for Management of Gastroesophageal Reflux p. 668
Health Insurance Coverage p. 257
Infection Control in Schools p. 335
Laws Regarding Child Abuse Reporting p. 391
Management of Diabetes in the School Setting p. 886
Newborn Screening for SCD p. 596
Nursing Genomics Competencies p. 614
Pain Management p. 323
Parental Presence During Procedures and Resuscitation p. 231
Pediatric Nursing Role in Disaster Planning p. 219
Schedule for Preventive Health Services p. 147
Screening Siblings for Vesicoureteral Reflux p. 710
Scoliosis Screening of Adolescents p. 838
Sports Preparticipation Screening p. 554
Standards for Pediatric Nursing Practice p. 2
Standards of Practice for Culturally Competent Nursing p. 38
Suicide Prevention p. 812
Sun Tanning p. 934
The National School Lunch Program p. 288
Using Chaperones to Examine Adolescents p. 105
Using the People-First Approach p. 47
